Abstract. Preeclampsia (PE), a hypertensive disorder during pregnancy, has adverse effects to both the mother and the fetus. Maternal inflammatory and vascular endothelial dysfunction are important factors in the pathogenesis of PE. The present study aimed to investigate the effects of estradiol (E2) on inflammatory and endothelial dysfunction in an N (omega)-nitro-L-arginine methyl ester (L-NAME)-induced rat model of PE. Adult pregnant female Sprague-Dawley rats were divided into four equal groups between days 7 and 11 of gestation and treated as follows: i) Pregnant rats receiving daily intraperitoneal (i.p.) injections of equal volume of 0.9% normal saline (NS) (Control group, n=12); ii) pregnant rats receiving daily i.p. injections of L-NAME at 50 mg/kg (L-NAME group, n=12); iii) pregnant rats receiving a daily i.p. injection of 50 mg/kg L-NAME and NS from day 11 (L-NAME + NS group, n=12); and iv) pregnant rats receiving daily i.p. injections of 50 mg/kg L-NAME and 100 μ g/kg/day E2 from day 11 (L-NAME + E2 group, n=12). On day 21, blood pressure (BP) and the level of 24-h urine protein in the maternal rats, fetal weight and percentage of stillbirths following a cesarean section were recorded. The activities of nitric oxide (NO) and inducible NO synthase (iNOS), the levels of inflammatory cytokines [interleukin (IL)-1 β , IL-6, interferon- γ and monocyte chemoattractant protein-1], adherence factors (CD49d, intracellular adhesion molecule 1 and lymphocyte function-associated antigen-1) and uterine angiogenic status (Fms-like tyrosine kinase-1, vascular cell adhesion molecule and matrix metalloproteinase 2/9) were also assessed. In addition, the histopathology of the placenta, the expression of estrogen receptor α 36 (ER α 36), ER α , ER β and G protein-coupled ER, as well as the activation of the

toll-like receptor 4 (TLR4) signaling pathway (TLR4, myeloid differentiation primary response 88, IL-1 receptor-associated kinase 4 and tumor necrosis factor receptor-associated factor 6) were evaluated by H&E staining, immunofluorescence and western blot assays. Treatment with L-NAME increased the BP, urine protein and rate of stillbirths and suppressed fetal weight compared with those in the control group. The L-NAME-induced effects were attenuated by the administration of E2. In addition, the administration of E2 decreased inflammation and NO levels and altered the uterine angiogenic status. The histological analysis of PE rat placenta in the E2-treated group confirmed the effects on biochemical parameters. Of note, E2 treatment significantly suppressed the TLR4 signaling pathway. In the rat model of PE, adverse outcomes including BP, fetal rat weight and proteinuria, high neonatal death rate, inflammatory response, oxidative stress and endothelial dysfunction were attenuated by exogenous E2 administration, which may present a novel approach for the clinical treatment of PE.

Introduction

Preeclampsia (PE) is a hypertensive condition that occurs during pregnancy. It is the major cause of maternal and perinatal death, premature birth and fetal growth restriction; the pathogenesis is complex and effective treatments are currently lacking (1,2). PE is a chronic disease, which frequently leads to multiple organ failure in the body of the pregnant woman, increases the production of reactive oxygen species, causes maternal inflammation and accelerates apoptosis, leading to an imbalance between the formation of normal placentation and pro-angiogenic factors (3). Previous studies have demonstrated that compared with non-pregnant females, those with normal pregnancy and patients with PE exhibit an inflammatory response, and that patients with PE exhibit excessive activation of the inflammatory response compared with normal pregnant subjects, including increased levels of inflammatory cytokines and products of oxidative stress (4,5). These results suggest that the inflammatory response has a crucial role in the pathogenesis of PE.

PE may lead to the dysfunction of vascular endothelial cells and increase endothelin secretion (6). Under normal conditions, the expression levels of intercellular adhesion molecule-1 (ICAM-1), vascular cell adhesion molecule-1 (VCAM-1)

Key words: preeclampsia, estradiol, inflammatory, endothelial dysfunction, toll-like receptor 4

and leukocyte function-associated antigen (LFA-1) are low, allowing neutrophils to roll along the endothelium without adhesion (7). However, the content of the pro-inflammatory cytokines tumor necrosis factor- α (TNF- α), interferon- γ (IFN- γ), interleukin (IL)-1 and monocyte chemoattractant protein (MCP)-1 is increased in the blood of patients with PE, which activates the molecular adhesion ligands on the vascular endothelium and leukocytes, thus significantly upregulating the levels of ICAM-1 and LFA-1, which interact with each other. Endothelial cells firmly bind to neutrophils to induce endothelial damage (7,8). In addition, vascular endothelial growth factor, placental growth factor and soluble Fms-like tyrosine kinase-1 (sFLT-1) lead to the general activation of the maternal inflammatory system, dysfunction of widespread endothelial cells and limitation of placental vascularization (9,10). Several studies have indicated that the secretion levels of multiple IL-1 family members in the maternal circulatory system and placental chorionic trophoblast cells are significantly increased (11,12), which serves an important role in promoting the development of PE.

Previous studies have described the effects of two steroid hormones, estrogen and progesterone, on vascular endothelial and smooth muscle cells (13). As a vascular endothelial protective factor maintains vascular tension and blood pressure stability, the decrease in estradiol (E2) levels may induce cardiovascular disease (14). It has been indicated that the levels of E2, propylene glycol and progesterone are abnormal in PE (15), but the details of these changes and specific effects remain elusive.

Although it has been reported that the expression of E2 is low in patients with PE, the exact mechanism remains unclear (16). The aim of the present study was to investigate whether treatment with exogenous E2 may improve inflammatory and endothelial dysfunction in a rat model of PE.

Materials and methods

Animals. A total of 48 adult Sprague-Dawley rats weighing 210–250 g (age, 7 weeks) were purchased from the Department of Experimental Zoology of Kunming Medical University (Kunming, China). All rats had *ad libitum* access to food and water and were maintained in a stable environment at $21\pm 3^{\circ}\text{C}$, $62\pm 3\%$ humidity and a 12-h light/dark cycle. The female rats were caged for 24 h with a male rat, and mating was confirmed by the presence of a vaginal plug and spermatozoa in the vaginal smear. The day on which insemination was detected was designated as day 1 of pregnancy. The protocols of the animal experiments followed the NIH Guide for the Care and Use of Laboratory Animals and the study was approved by the Experimental Animal Ethics Committee of Kunming Medical University and the Commission for Animal Experimentation of The People's Hospital of the Xishuangbanna Dai Nationality Autonomous Prefecture.

Treatment and experimental grouping. The rats were randomly divided into four groups on day 7 as follows: i) Normal pregnant rats receiving daily intraperitoneal (i.p.) injections of equal volume of 0.9% normal saline (NS) (Control group, $n=12$); ii) pregnant rats receiving daily i.p. injections of 50 mg/kg L-NAME (L-NAME group, $n=12$); iii) pregnant rats receiving

daily i.p. injections of 50 mg/kg L-NAME and NS from day 11 (L-NAME + NS group, $n=12$); iv) pregnant rats receiving daily i.p. injections of 50 mg/kg L-NAME plus 100 $\mu\text{g}/\text{kg}/\text{day}$ E2 from day 11 (L-NAME + E2 group, $n=12$).

On days 13 and 21 of gestation, 24-h urine of rats was collected using metabolic cages (Yuyan Instruments) for the determination of urinary protein. The level of urine protein was measured using a Rat Urinary Protein kit (Sigma-Aldrich; Merck KGaA).

Blood pressure (BP) measurement. On days 13 and 21, rat BP was measured using the non-invasive tail cuff method after rats had been pre-warmed in a heating chamber at 37°C for 15 min. The BP measurement was repeated five times, and the mean value for each rat was obtained.

Determination of fetal weight and rate of stillbirths. On day 21 of pregnancy, rats were anesthetized with 2% sodium pentobarbital at the dose of 50 mg/kg and placed in the supine position for delivery by cesarean section. The following parameters were determined: Litter size, number of stillbirths and surviving neonates. Subsequently, fetal weight was determined by dividing the total weight of all pups and placentas in each litter by the number of pups in that litter. Under terminal anesthesia, blood samples were collected from the maternal rat by intracardiac puncture for ELISA and placenta tissue was harvested for histopathologic analysis; placental homogenate was prepared for mRNA and protein detection. At the end of the experiment, the surviving pups were euthanized with 2% sodium pentobarbital.

H&E staining. For the histopathologic analysis of the placenta, tissue samples were fixed in 10% phosphate-buffered formalin for 48 h at room temperature, embedded in paraffin, cut into 5-mm sections and placed on slides. Subsequently, the sections were stained with 0.5% H&E solution and examined under a light microscope (Olympus Corporation) under $\times 200$ magnification. Five visual fields of the placenta tissue on each section were selected randomly.

Cytokine determination using ELISA. Cytokine levels of IL-1 β , IL-6, IFN- γ , MCP-1 and sFlt-1 in the serum of each maternal rat and the activity levels of nitric oxide (NO) and inducible NO synthase (iNOS) in the homogenate of placenta tissue were determined by ELISA with rat ELISA kits IL-1 β (ml003057), IL-6 (ml102828), IFN- γ (ml064291), MCP-1 (ml002960), sFlt-1 (ml059017), NO (ml059000) and iNOS (ml003127) purchased from Shanghai Enzyme-linked Biotechnology Co., Ltd. according to the manufacturer's protocols. The absorbance in each group was detected using a microplate reader at 450 nm.

Western blot analysis. Total proteins were extracted from the placenta tissue homogenates using RIPA lysis buffer (Sigma-Aldrich; Merck KGaA), and a bicinchoninic acid protein assay kit (Pierce; Thermo Fisher Scientific, Inc.) was used to determine the protein concentration. Proteins (45 $\mu\text{g}/\text{lane}$) were separated by 8–10% SDS-PAGE and transferred onto polyvinylidene fluoride membranes (Beyotime Institute of Biotechnology). The membranes were blocked

in 5% skimmed milk at room temperature for 1 h prior to incubation with the primary antibodies against IL-1 β (cat. no. ab2105; 1:1,000; Abcam), IL-6 (cat. no. 12153; 1:1,000; Cell Signaling Technology, Inc.), IFN- γ (cat. no. 3159; 1:1,000; Cell Signaling Technology, Inc.), MCP-1 (cat. no. ab25124; 1:2,000; Abcam), CD49D (cat. no. ab75760; 1:1,000; Abcam), ICAM1 (cat. no. ab171123; 1:1,000; Abcam), LFA-1 (cat. no. ab52895; 1:2,000; Abcam), sFlt-1 (cat. no. ab9540; 1:1,000; Abcam), VCAM1 (cat. no. ab174279; 1:1,000; Abcam), MMP2 (cat. no. ab92536; 1:2,000; Abcam), MMP9 (cat. no. ab137867; 1:1,000; Abcam), ER α (cat. no. ab16460; 1:1,000; Abcam), ER β (cat. no. ab3576; 1:1,000; Abcam), GPER (cat. no. ab39742; 1:1,000; Abcam), TLR4 (cat. no. ab217274; 1:500; Abcam), myeloid differentiation primary response 88 (MyD88; cat. no. ab2064; 1:500; Abcam), phospho (p)-IL-1 receptor-associated kinase 4 (IRAK4; cat. no. 11927, 1:1,000; Cell Signaling Technology, Inc.), IRAK4 (cat. no. 4363; 1:1,000; Cell Signaling Technology, Inc.), TNF receptor-associated factor 6 (TRAF6; cat. no. ab33915; 1:2,000; Abcam) and ER α 36 (cat. no. CY1109; 1:1,000; Cell Applications, Inc.) at 4°C overnight. Subsequently, the membranes were incubated with horseradish peroxidase-conjugated goat anti-mouse (cat. no. ab205719; 1:2,000; Abcam) or anti-rabbit (cat. no. ab205718; 1:2,000; Abcam) IgG secondary antibodies for 2 h at room temperature. The membranes were visualized using an enhanced chemiluminescence system (Beyotime Institute of Biotechnology) and densitometry analysis was performed using Image J software (version 1.47; National Institutes of Health). GAPDH (cat. no. ab181602; 1:10,000; Abcam) expression was used as an internal control.

Total RNA isolation and reverse transcription-quantitative PCR (RT-qPCR). Total RNA was extracted from the placenta tissue homogenate of each rat using TRIzol[®] reagent (Invitrogen; Thermo Fisher Scientific, Inc.). Total RNA was reverse-transcribed into cDNA using SuperScript[™] III Reverse Transcriptase (Invitrogen; Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol. The reverse transcription conditions were 10 min at 25°C, 30 min at 48°C and 5 min at 95°C. RT-qPCR was performed on a 7500 Fast Real-Time PCR System Light Cycler (Applied Biosystems; Thermo Fisher Scientific, Inc.) using a 20- μ l reaction system that was incubated as follows: 95°C for 2 min, followed by 40 cycles of 95°C for 20 sec and 72°C for 30 sec. The PCR was repeated three times and the primer sequences were as follows: ER α 36 forward, 5'-CCAAGAATGTTCAACCACAACCT-3' and reverse, 5'-GCACGGTTCATTAACATCTTTCTG-3'; GAPDH forward, 5'-ACAGTCAGCCGCATCTTCTT-3' and reverse, 5'-GACAAGCTTCCCGTTCTCAG-3'. The relative expression of mRNAs was determined using the 2^{- $\Delta\Delta$ Cq} method (17) with normalization to GAPDH expression.

Immunofluorescence (IF) staining of rat placenta tissue. IF staining was performed on placenta tissue by cutting 5 μ m-thick paraffin sections and incubating them with an antibody against ER α 36 (cat. no. CY1109; 1:100; Cell Applications Inc.) at 4°C overnight. The sections were washed and incubated at room temperature for 1 h with an Alexa Fluor 488-conjugated anti-rabbit IgG secondary antibody (cat. no. ab150077; 1:500; Abcam). The nuclei were stained with

DAPI (Invitrogen; Thermo Fisher Scientific, Inc.). The images were captured under a TCS SP5 confocal microscope (Leica Microsystems; magnification, x200). The intensity of green fluorescence in the images represents the protein expression of ER α 36.

Statistical analysis. Data are expressed as the mean \pm standard deviation. Statistical analyses were performed using SPSS software (version 17.0; SPSS, Inc.). The statistical significance of differences among multiple groups was determined by one-way analysis of variance followed by Dunnett's post-hoc test. The correlation between sFlt-1 expression and the level of other cytokine levels, including IL-1 β , IL-6, IFN- γ and MCP-1, was examined using Pearson's correlation analysis. Each experiment was performed at least three times. P<0.05 was considered to indicate statistically significant difference.

Results

Effects of E2 on blood pressure and urine protein content. No significant difference in systolic BP was observed among the four groups on day 13 (P>0.05; Fig. 1A). On day 21, BP in the L-NAME group was higher compared with that in the control group (P<0.05; Fig. 1A), but it was decreased by E2 treatment (P<0.05; Fig. 1A). These results suggested that E2 treatment prevented the elevation of BP in rats with PE (18).

Similarly, no significant difference in 24-h urine protein was observed among the four groups on day 13 (P>0.05; Fig. 1B). However, on day 21, the 24-h urine protein content was significantly higher in the L-NAME group compared with that in the control group (P<0.001; Fig. 1B), whereas the L-NAME + E2 group exhibited a significant decrease in urine protein content compared with that in the L-NAME group (P<0.01; Fig. 1B). These results suggested that E2 was effective in preventing the elevation of urine protein in rats with PE.

Effects of E2 on fetal weight and the rate of stillbirths. Compared with the control group, a significant decrease fetal weight was observed in the L-NAME group (P<0.01; Fig. 1C). However, E2 treatment restored the weight of neonates in the L-NAME + E2 group to the level in the control group (P<0.01; Fig. 1C), whereas no significant differences were identified between the L-NAME and L-NAME + NS groups. In addition, the rate of stillbirths in the L-NAME group was increased compared with that in the control group (P<0.001; Fig. 1D), whereas the L-NAME + E2 group exhibited a decrease compared with the L-NAME group (P<0.001; Fig. 1D); however, E2 treatment did not restore the number of stillbirths to the control level. Therefore, compared with that in the normal pregnant rats in the control group, the rate of stillbirths in the L-NAME + E2 group was still high. The results demonstrated that treatment with E2 partially protected the fetuses of rats with PE against the effects of L-NAME, increasing the fetal weight and reducing the rate of stillbirths.

Effects of E2 on placental histopathology. Histopathological examination with H&E staining revealed degeneration in the placenta from the rats in the L-NAME and L-NAME + NS

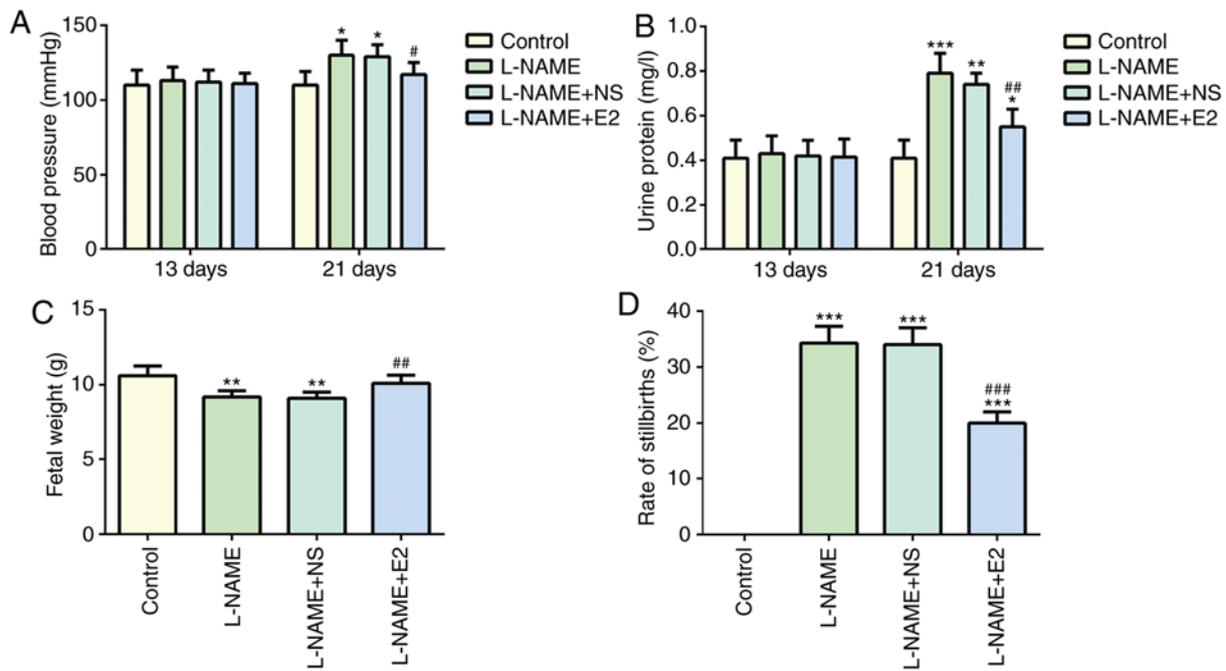

Figure 1. Effects of E2 on the adverse pregnancy outcome of rats with preeclampsia. (A) Blood pressure and (B) urine protein for 24 h on days 13 and 21 of gestation in rats in the four groups. (C) Fetal weight and (D) rate of stillbirths on day 21 of gestation in the four groups. $n=12$ rats/group. * $P<0.05$, ** $P<0.01$ and *** $P<0.001$ vs. control; # $P<0.05$, ## $P<0.01$ and ### $P<0.001$ vs. L-NAME and L-NAME + NS. L-NAME, N (omega)-nitro-L-arginine methyl ester; NS, normal saline; E2, estradiol.

groups, including necrotic changes and inflammatory cell infiltration (Fig. 2A). However, these were absent in the L-NAME + E2 group. Therefore, E2 treatment reduced inflammatory infiltration in placenta tissue of rats with PE.

Effects of E2 on NO levels and iNOS activity in placental homogenate. ELISAs were performed to detect NO levels and iNOS activity in the placental homogenate using NO and iNOS kits for rats. NO and iNOS levels were increased in the L-NAME group compared with those in the control group ($P<0.001$; Fig. 2B and C). However, the NO and iNOS activity did not significantly differ between the L-NAME and L-NAME+NS groups. E2 administration partially inhibited the L-NAME-induced elevation of placental NO and iNOS activity ($P<0.001$; Fig. 2B and C).

Effects of E2 on inflammatory cytokines in serum and placental homogenate. The levels of serum IL-1 β (Fig. 3A), IL-6 (Fig. 3B), IFN- γ (Fig. 3C), MCP-1 (Fig. 3D) and sFlt-1 (Fig. 3E) in the L-NAME group were significantly higher compared with those in the control group. Following treatment with E2, the L-NAME + E2 group exhibited a decrease in these inflammatory cytokines in the serum compared with those in the L-NAME and L-NAME + NS groups. In addition, the protein expression of inflammatory cytokines in the placenta homogenate was detected using western blot analysis (Fig. 3F). The trends of the placental protein expression of these inflammatory cytokines in the different groups were consistent with the serum levels. The correlation between sFlt-1 and IL-1 β , IL-6, IFN- γ and MCP-1 expression in serum was assessed using Pearson's correlation analysis and the results revealed that sFlt-1 had a tendency towards a weak positive

correlation with IL-1 β (Fig. 3G, $R^2=0.3647$, $P=0.0376$), IL-6 (Fig. 3H, $R^2=0.3372$, $P=0.0477$), IFN- γ (Fig. 3I, $R^2=0.3863$, $P=0.0310$) and MCP-1 (Fig. 3J, $R^2=0.5132$, $P=0.0088$). These results indicated that in rats with PE, E2 administration effectively suppressed the inflammatory response.

Effects of E2 on adhesion factors and angiogenic factors in the placenta. Western blot analysis indicated that treatment with L-NAME increased the expression levels of CD49d, ICAM1 and LFA-1 compared with those in the control group ($P<0.001$; Fig. 4A and B), whereas E2 treatment decreased their expression levels compared with those in the L-NAME and L-NAME + NS groups ($P<0.001$; Fig. 4A and B). In addition, the protein levels of MMP2, MMP9 and VCAM1 were elevated in the L-NAME group compared with those in the control group ($P<0.001$; Fig. 4C and D); however, the expression of these proteins was downregulated in the L-NAME + E2 group compared with that in the L-NAME and L-NAME + NS groups ($P<0.001$; Fig. 4C and D). Therefore, E2 treatment reduced endothelial dysfunction in rats with PE.

Effects of E2 on the expression of ER α 36 in the placenta. As presented in Fig. 5A, compared with that in the control group, L-NAME treatment significantly decreased the mRNA levels of ER α 36 ($P<0.001$), which were partially restored by E2 treatment ($P<0.01$). The results of the western blot analysis of the protein levels of ER α 36 were consistent with the RT-qPCR results (Fig. 5B). The protein levels of ER α , ER β and GPER were also assessed by western blot analysis; treatment with L-NAME induced a decrease in the protein expression of ER α and ER β , whereas E2 partially reversed

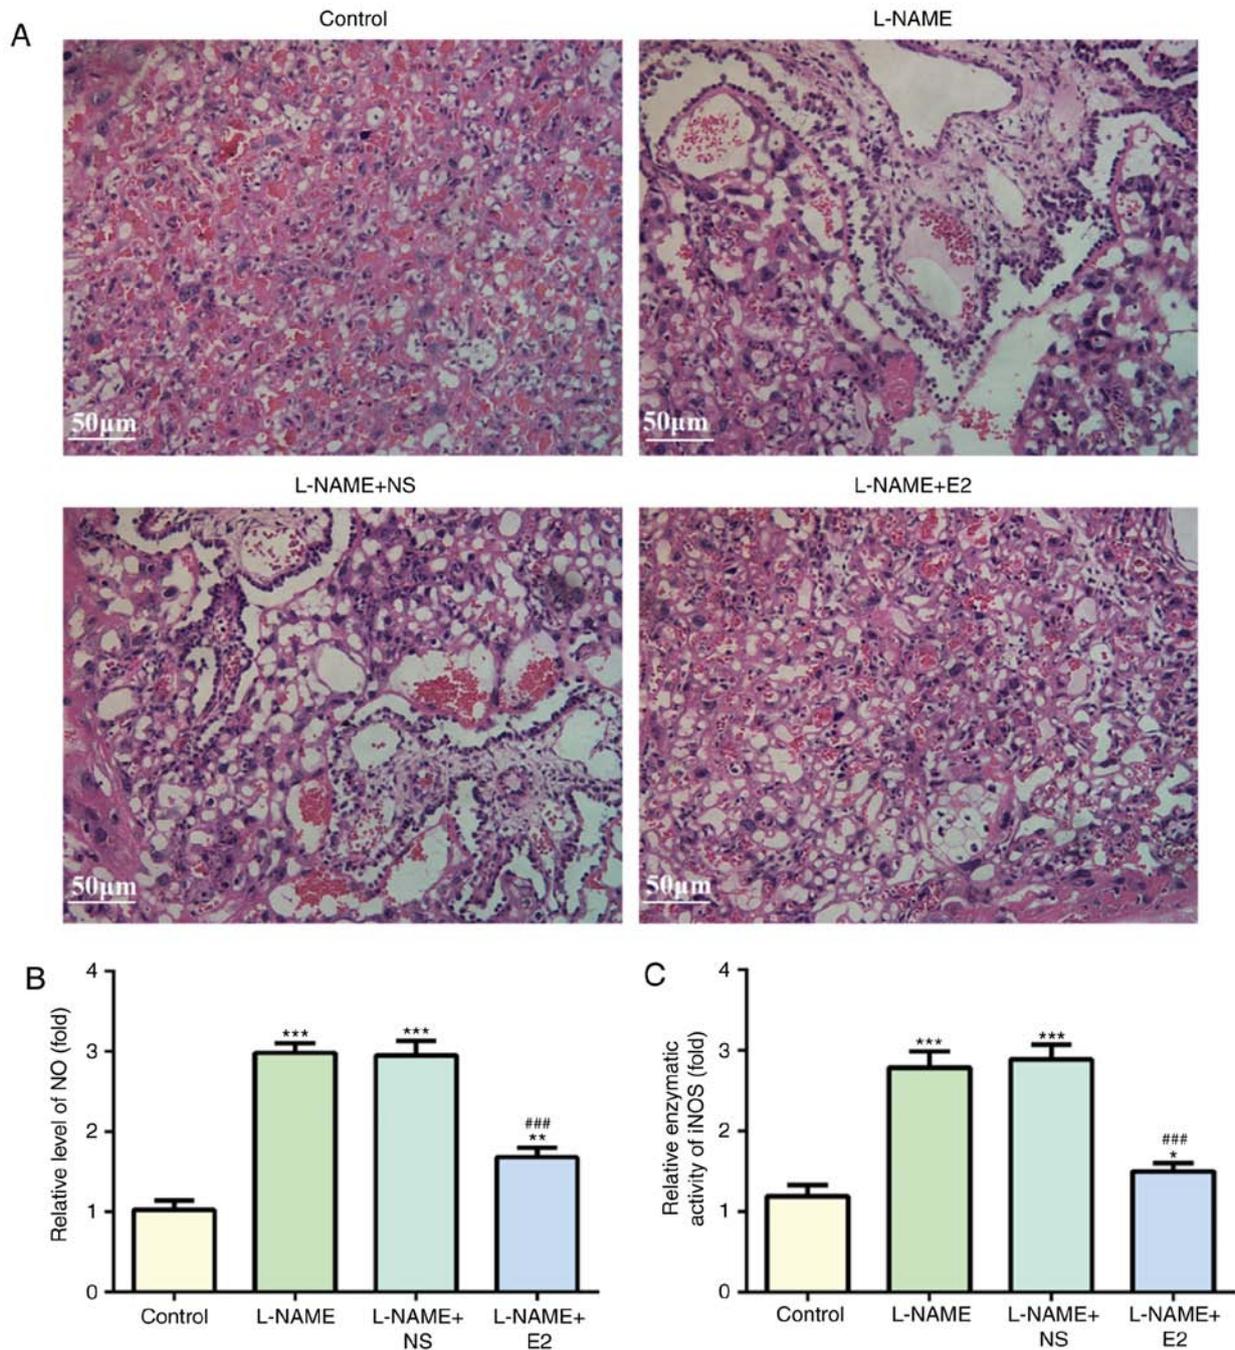

Figure 2. Effects of E2 on placenta damage, NO level and iNOS activity. (A) Hematoxylin and eosin staining of placenta. Magnification, x200. (B) Relative NO level and (C) iNOS activity in placenta. n=12 rats/group. *P<0.05, **P<0.01 and ***P<0.001 vs. control; ###P<0.001 vs. L-NAME and L-NAME + NS. L-NAME, N (omega)-nitro-L-arginine methyl ester; NS, normal saline; E2, estradiol; NO, nitric oxide; iNOS, inducible NO synthase.

these effects (Fig. 5C). However, GPER expression was not affected by L-NAME or E2, and no significant differences were observed among the four groups. In addition, the IF assay indicated high expression of ER α 36 (green) in the placenta of the control group, whereas L-NAME treatment caused a significant downregulation of ER α 36 expression (Fig. 5D). By contrast, ER α 36 expression (green) was upregulated in the L-NAME + E2 group compared with that in the L-NAME and L-NAME + NS groups (Fig. 5D). These results indicated that the combination of E2 with ERs (especially ER α 36) was involved in the regulation of inflammation and endothelial function in rats with PE.

Effects of E2 on the expression of key molecules involved in the TLR4 signaling pathway in the placenta. Western blot analysis indicated that following treatment with L-NAME, the expression levels of TLR4, MyD88, p-IRAK4 and TRAF6 were increased compared with those in the control group (P<0.001; Fig. 6); however, E2 administration significantly reduced the expression levels of these proteins compared with those in the L-NAME and L-NAME + NS groups (P<0.001; Fig. 6). Of note, total (t)-IRAK4 expression was not significantly altered among the four groups. Overall, these results suggested that the TLR4 signaling pathway may serve a functional role in rats with PE.

Data was presented as mean \pm SD (n=12 per group). *P<0.05, **P<0.01 and ***P<0.001 vs. control; ##P<0.01 and ###P<0.001 vs. L-NAME and L-NAME + NS.

Discussion

The novel finding of the present study was that treatment with E2 attenuated the adverse pregnancy outcomes in a rat model of L-NAME-induced PE, and these effects were associated with a decrease in inflammation and endothelial dysfunction, as well as histological improvement in the placenta. In addition, these

results were supported by a significant decrease in the rate of stillbirths and the levels of NO and iNOS, accompanied by a reduction of the inflammatory cytokines IL-1 β , IL-6, IFN- γ , MCP-1 and sFlt-1. The L-NAME-induced rat model of PE is accepted as a method of inducing experimental hypertension, resulting in a condition similar to clinical PE (19). To the best of our knowledge, the present study was the first to explore

with PE (20,21), which were consistent with the results of the present study. The levels of BP, urine protein and fetal death were increased, whereas fetal body weight was decreased in the L-NAME group in the present study. Hypertension is one of the pathophysiological factors resulting in PE and injuries of the systematic inflammatory response (22). E2 improved the biochemical indexes and neonatal outcome by reducing BP, urine protein and the rate of stillbirths, increasing fetal weight and attenuating pathological injury, which indicated that the improvement of PE was associated with E2 treatment. Previous studies have demonstrated that L-NAME induced an increase in BP in rats and that the lower production of iNOS and NO participated in the adaptive reconstruction of vasculature occurring during normal pregnancy and served an important role in maintaining constant vascular tension

and the stability of blood pressure (23,24). Akram *et al* (25) have reported that estrogen serves a protective role in PE by affecting the renin-angiotensin-aldosterone system to increase the blood volume and regulating the activity of endothelial NO synthase to induce the release of vasoconstrictors. In the present study, treatment of pregnant rats with L-NAME elevated the production of NO and iNOS to cause oxidative stress and impair endothelial function in early hypertension. The results of the present study also suggested that E2 may be a beneficial treatment for the symptoms of PE in agreement with a previous study (25).

The high levels of IL-1β, IL-6, IFN-γ and MCP-1 in the serum and placenta tissue of rats with PE may be linked to the inflammatory response, suggesting that inflammatory cytokines may participate in the adverse events in PE (26). In

The expression and statistical analysis of TLR4, MyD88, p-IRAK4, t-IRAK4 and TRAF6 by western blotting. n=12 rats/group. *P<0.05, **P<0.01 and ***P<0.001 vs. control; ###P<0.001 vs. L-NAME and L-NAME + NS. E2, estradiol; L-NAME, N (omega)-nitro-L-arginine methyl ester; NS, normal saline; TLR4, toll-like receptor 4; MyD88, myeloid differentiation primary response 88; IRAK4, interleukin-1 receptor-associated kinase 4; p, phospho; t, total; TRAF6, TNF receptor-associated factor 6.

the present study, treatment with E2 resulted in a reduction in the levels of IL-1 β , IL-6, IFN- γ and MCP-1 in the serum and placenta of rats with PE, indicating the anti-inflammatory effect of exogenous estrogen. The major alterations associated with PE are likely to trigger local oxidative stress, and re-oxygenation may expand the local effects, including the formation of reactive oxygen species, activation of the maternal inflammatory system and acceleration of apoptosis that may limit the establishment of normal placentation and cause imbalance between pro-angiogenic factors, including sFLT-1 and VCAM-1 (3). In addition, PE may be associated with increased production of MCP-1 and IL-8, which are regulated by signaling mechanisms sensitive to oxidative stress (27). Inflammation is closely associated with angiogenesis. Therefore, the correlation among these factors was analyzed in the present study, and a weak positive correlation between sFLT-1, inflammatory cytokines and MCP-1 was revealed, indicating that sFlt-1 and MCP-1 may lead to the general activation of the maternal inflammatory system, endothelial dysfunction and the limitation of placental vascularization. In addition, E2 may decrease the levels of sFlt1 and MCP-1 to reverse endothelial dysfunction and restricted placental angiogenesis, which may achieve effective treatment of PE.

High expression of ICAM-1 has been previously detected in epithelial cells and the stroma of abortion-prone fetuses in maternal rats, which causes increased recruitment of lymphocytes expressing LFA-1 from the blood into the uterus (28). The levels of IL-1 β , TNF- α and IFN- γ are increased in lymphocytes, and stress further increases the expression of ICAM-1 in

the endothelium (29). Inhibition of ICAM-1/LFA-1-mediated intercellular adhesion events may restore the fetal immune acceptance in challenged pregnancies (28). Studies have reported that ICAM-1 and VCAM-1 are increased in the serum or plasma of patients with PE (30). CD49d, an inflammation-associated adhesion molecule expressed on neutrophils and monocytes, binds to VCAM-1 (31). The present result exhibited that L-NAME induced an increase of CD49d, ICAM-1, LFA-1 and VCAM-1 expression levels, which were significantly reversed by E2 administration. This indicated that E2 may alleviate endothelial dysfunction in PE rats by reducing the adhesion of placental tissue and the process of angiogenesis.

ER α 36, which is a membrane variant of ER α , is also affected by the dysregulation of estrogen signaling (32). ER α has been demonstrated to suppress the activity of ER α 36 promoter in an estrogen-independent manner (33). ER α 36 has been identified as a mediator of E2 action in the malignant liver and may be involved in the occurrence and development of various tumors (34,35). Consistent with the previous results, the results of the present study indicated that the induction of E2 after L-NAME treatment suppressed the expression of ER α 36, ER α and ER β in the placenta of rats with PE compared with that in normal pregnant rats. E2 administration induced upregulation of ER α 36, ER α and ER β expression compared with that in the L-NAME group. Among the ERs, the changes in ER α 36 levels were the most significant. The expression changes of other estrogen receptors may eventually lead to changes in ER α 36 expression, which was why

ER α 36 was selected as the main research object of the present study. A previous study reported that E2 suppressed the binding activity of NF- κ B mediated by ER α 66 and reduced the expression of MMP2, MMP9, cyclin A and cyclin D1, resulting in cell cycle arrest and promoting cell apoptosis (36). Apoptotic processes and endothelial dysfunction are common in PE (3). The results of the present study indicated that that E2 suppressed the expression of MMP9, MMP2 and VCAM-1 in placental tissue induced by L-NAME treatment. ER α 36 has been demonstrated to be located in the cytoplasm as well as on the cell surface, where it mediates non-genomic estrogen signaling through cross-talk with growth factor receptors and other signaling molecules (including mitogen-activated protein kinase/ERK and PI3K/AKT) to promote cell proliferation, invasion and migration, as well as resistance to endocrine therapy (37). Therefore, it was hypothesized in the present study that E2 may bind to ER α 36 to regulate the expression of the above factors through certain signaling pathways, such as the TLR4 signaling pathway.

In the present study, the anti-inflammatory, antioxidant and anti-vascular dysfunction properties of E2 were indicated to be, at least in part, mediated by the suppression of the TLR4 pathway through the inhibition of MyD88 and TRAF6 expression, as well as phosphorylation of IRAK4. A previous study has reported that the TLR4 signaling pathway serves an important role in autoimmune disease (38) and the inflammatory response and pathological damage associated with various diseases in humans (39,40). MyD88 and TRAF-6 are important intracellular adaptor proteins that function as effectors of the TLR4 signaling cascade (41). MyD88 activates and phosphorylates IRAK4, leading to the recruitment of TRAF6 and promoting inflammation (42). The intracellular signaling cascade is activated by TLR4 by recruiting IRAK4 to the membrane (43). The TLR4-dependent signaling pathway has been reported to be detrimental to trophoblast function (44). These previous studies are in accordance with the results of the present study, as the TLR4/MyD88/IRAK4/TRAF6 signaling pathway was activated in rats with PE. The results of the present study suggested that the regulation of the TLR4/MyD88/IRAK4/TRAF6 pathway may be involved in the effects of E2 against L-NAME-induced pathological processes of PE. The binding of E2 to ER α 36 may participate in the regulation of angiogenesis and inflammation by mechanisms dependent on TLR4 activation in PE.

In summary, the results of the present study demonstrated that E2 may improve adverse pregnancy outcomes induced by L-NAME in rats. The protective effects of E2 may be partially exerted by binding to ER α 36, regulation of inflammatory, adherence and placental angiogenic factors and deactivation of TLR4/MyD88/IRAK4/TRAF6 signaling. Therefore, E2 may be a potential therapeutic for treating PE.

Funding

No funding was received.

Availability of data and materials

The datasets used and analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions

ZHL designed the experiments and wrote the manuscript. ZHL, JJ and YYS performed the experiments and analyzed the data. All authors read and approved the final version of the manuscript.

Ethics approval and consent to participate

The protocols of the animal experiments followed the NIH Guide for the Care and Use of Laboratory Animals and were approved by the Experimental Animal Ethics Committee of Kunming Medical University (Kunming, China) and the Commission for Animal Experimentation of The People's Hospital of the Xishuangbanna Dai Nationality Autonomous Prefecture.

Patient consent for publication

Not applicable.
