Abstract. Preeclampsia (PE) in pregnancy is associated with vitrified-thawed embryo transfer. Pleiotrophin (PTN) is important in inflammation via its receptors. The aim of the present study was to determine the effect of PTN on the risk of PE following embryo transfer. An enzyme-linked immunosorbent assay was performed to determine the levels of tumor necrosis factor (TNF)- α and PTN in serum. The knockdown of PTN was conditionally induced by tamoxifen (tax) treatment. The tail-cuff method and Bradford assay were used to monitor blood pressure and the level of urine protein, respectively. The expression patterns of PTN, receptor protein tyrosine phosphatase β/ζ , (RPTP β/ζ), syndecan-1 (SDC1), syndecan-3 (SDC3) and anaplastic lymphoma kinase (ALK) were determined by immunohistochemistry (IHC). Western blot analysis was performed to evaluate the expression level of PTN and its receptors. The risk of PE was elevated following embryo transfer in clinical and in the tax/PTN^{-/-} group. It was found that the level of PTN increased when pregnancy progressed in normal conditions, however, the level of PTN was reduced in the PE mice. In addition, increases in TNF- α , blood pressure and urine protein were more marked in the PE mice that lacked PTN, compared with those in other PE mice. In addition, overlapping expression of PTN and its receptors in villous mesenchyme and fetal macrophages were identified using an IHC assay. However, the positive staining of PTN and its receptors was weaker or even absent in the PE mice. The protein level of RPTP β/ζ was lower in the PE mice that lacked PTN than that in the other PE mice. The knockdown of PTN increased the risk of PE following vitrified-thawed embryo transfer, in which its receptors, particularly RPTP β/ζ , may be involved.

Introduction

With increasing problems of infertility (1,2), the number of initiated treatments using assisted reproductive technology (ART) is rising (3). ART is a reproductive technology developed to achieve pregnancy as a fertility treatment. ART contributed to ~1.6% of births in the United States in 2013 (4). At present, embryo cryopreservation is an essential technology used in ART (5), and it is important in ART as, rather than immediately transferring into the uterus, embryo cryopreservation allows supplementary embryos to be reserved for later pregnancy attempts (6,7). Controlled-rate freezing and vitrification are two cryopreservation techniques that prevail in embryo cryopreservation. Although the former was the first to be applied and developed, the latter has gained increased attention due to its increasingly efficacious clinical outcomes (8). Vitrification is a cryopreservation method whereby the embryo can be cooled at ultra-fast rates (9). The main advantage of vitrification is the absence of ice crystal formation, which reduces the damage accompanying chilling. Furthermore, it does not rely on expensive programmable freezing equipment (10-12). Although the proportion of births has been increased by embryo cryopreservation due to significant improvements in technology (13), adverse perinatal outcomes have been commonly observed in pregnancies following ART, compared with those women who conceive naturally and with preeclampsia (PE) (14,15). In addition, compared with fresh embryo transplantation, increased risk of PE in embryo cryopreservation has been reported (15).

As an obstetrical complication, PE is a condition that emerges after the 20th week of gestation. This disorder accounts for preterm deliveries and subsequent neonatal morbidity (16-18). PE is a primary contributor to the poor prognosis of the mother and the baby, and it is usually accompanied by the occurrence of high blood pressure, an increase in the level of urine protein and other severe organ impairments (19,20). In addition, coagulant dysfunction also involved in PE (21). A previous study reported a maternal mortality rate of 50,000-60,000 caused by PE each year worldwide (22). Although extensive efforts have been made, the exact etiology of PE remains to be elucidated. It has been suggested that PE is a systemic maternal inflammatory response in which oxidative stress occurs. According to previous studies (23,24), the pathogenesis of PE can be divided into two stages, namely abnormal

Key words: vitrification embryo cryopreservation, preeclampsia, pleiotrophin, receptors

placentation and endothelial dysfunction. The implantation of placenta in early pregnancy is mainly realized by the trophoblast infiltration of spiral arteries, proteolytic enzymes and the activity of adhesion molecules (24).

Multiple growth factors are involved in the progress of PE (25). As a secreted cytokine that serves as heparin-binding growth factor, pleiotrophin (PTN) is associated with various cellular events via distinct receptors (26), including inflammatory conditions (27). The expression of PTN, receptor syndecan-1 (SDC1) and receptor protein tyrosine phosphatase β/ζ (RPTP β/ζ) are found in the placenta, and are critical to the infiltration of trophoblast cells and damage of the vascular endothelium. PTN/RPTP β/ζ also regulates the oxidative stress response (26). As two of the receptors of PTN, anaplastic lymphoma kinase (ALK) and syndecan-3 (SDC3) are essential to human placentation (26). However, to the best of our knowledge, the effect of PTN on and its receptors in PE in pregnancy following transplantation of embryo cryopreservation by vitrification have not been investigated or presented.

Therefore, the objective of the present study was to investigate the effect of embryo cryopreservation by vitrification in terms of the risk of PE. The effect of PTN knockout on PE in pregnancy following vitrified-warmed embryo transfer was also examined. This may reveal a biomarker for the prediction of pregnancy outcome following transplantation of embryo cryopreservation.

Materials and methods

Patient samples. The 188 patients recruited were those who received ART treatment between April, 2012 and November, 2016 at Luoyang Central Hospital Affiliated to Zhengzhou University (Luoyang, China). All protocols associated with humans in the present study were approved by the Review Board of Luoyang Central Hospital Affiliated to Zhengzhou University. All participants provided permission to cooperate to undertake the relevant study and provided written informed consent. The study included 188 cycles. The inclusion criteria were as follows: Age, 20-38 years, embryo freezing storage period between 30 and 1,080 days, vitrification was applied as an embryo cryopreservation method. Patients with a history of chronic hypertension (and/or used antihypertensive medication prior to pregnancy), multifetal gestation, or metabolic dysfunctions were excluded from the study. According to standard criteria (26), PE was defined as gestational hypertension with proteinuria.

Animals. The study was performed under the approval of the Animal Ethics Committee of Luoyang Central Hospital Affiliated to Zhengzhou University. The PTN^{-/-} mice were generated by deleting exons 2-4 on a background of 129/OlaxC57BL/6J as described in two previous studies (28,29). The animals (614 female mice, 8-10 weeks old, weighing 18-25 g) obtained from Nanjing Biomedical Research Institute (Nanjing, China) were divided into [WT (304 mice) group and PTN^{-/-} (310 mice) group] for the preparation of false pregnancy. The animals had free access to food and water and were housed at 22°C (60-70% humidity, 12 h light/12 dark). The average body weight of the mice in each group was between 20 and 25 g

(8-10 weeks of age). The genotype of PTN^{-/-} mice was identified using a polymerase chain reaction method as previously described (30). The primers used were as follows: Forward, 5'-GATTGAACAAGATGGATTGC-3' and reverse, 5'-CATTTAGGCAAACAGGAAGGACG-3'. The genomic DNA extracted from tails of PTN^{-/-} (a total of 310 mice) and WT mice (a total of 304 mice) was used as the template. The temperature protocols was set as: 94°C, 5 min; 35 cycles of 94°C, 30 sec, 63°C, 30 sec, 72°C 1 min; final extension at 72°C, 10 min.

In vitro fertilization. An intraperitoneal injection of permanent-magnet synchronous generator (PMSG) (5 IU/mice; Ningbo Sansheng Pharmaceutical Co., Ltd., Ningbo, China) was administered to female mice (75 mice, 8 weeks old, weighing 18 g). After 48 h, human chorionic gonadotropin was then injected (5 IU/mouse; Ningbo Sansheng Pharmaceutical Co., Ltd.). The eggs were collected 14 h later. In brief, the female mice (weight, 18 g) were sacrificed by cervical dislocation and following disinfection, the fallopian tubes were rapidly isolated and washed in PBS working buffer. The abdomen of the fallopian tube was then opened with ophthalmic forceps under a stereomicroscope. The egg granule cell complex was collected and washed in PBS and HTF medium (Quinn's; SAGE-*In vitro* Fertilization, Inc., Trumbull, CT, USA). The sperm from the cauda epididymis of male mice (25 mice, 8 weeks old) were incubated in HTF medium covered with paraffin oil (Sigma; EMD Millipore, Billerica, MA, USA) at 37°C for 1 h (5% CO₂ atmosphere). Following this treatment, the sperm (final sperm concentration, 2.0x10⁶/ml) were co-cultured with eggs droplets (30-40/droplets) for 4-6 h for *in vitro* fertilization (fertilization rate, 74.36%). The fertilized eggs in cleavage medium covered with paraffin oil (Sigma; EMD Millipore) were maintained for 36-48 h in order to acquire four-cell stage embryos. Blastula medium (BM; SAGE-*In vitro* Fertilization, Inc.) was used to culture four-cell embryos for obtaining blastocysts.

Vitrified freezing. In brief, frozen liquid containing vitrification solution (VS) solution and equilibration solution (ES) (both from Kitazato, Tokyo, Japan) were prepared 30 min in advance. The blastocysts were maintained in ES for 10 min and in VS for 30 sec. Finally, the embryos were transferred onto the top of Cryotop (Kitazato) with a minimal volume of embryo solution attached, which were immediately stored in liquid nitrogen. The contact time of the embryo with the VS liquid was between 30 and 60 sec. For thawing, the blastocysts maintained in Cryotop were collected and directly immersed in thawing solution for 60 sec, and then in diluent solution for 60 sec, in washing solution (WS)1 for 3 min, and in WS2 for 3 min. The blastocysts were then transferred into BM covered with mineral oil for 1.5-2.5 h.

Blastocyst transfer. The male mice (8 weeks old, weighing 20-22 g, Nanjing Biomedical Research Institute) were vascularized under the anesthesia status. The mice were anesthetized by the intravenous administration of sodium pentobarbital solution (2 mg/ml; Solarbio, Beijing, China) (30-50 mg/kg body weight). In brief, following anesthesia, the mice were disinfected with 70% ethanol. The vas deferens of the mice was 'picked up' with tweezers and was ligated. The vas deferens was then cut off in the middle of the two ligatures.

The healed vasectomized male mice were mated with estrous female mice from the WT group and PTN^{-/-} group as already described. The following morning, the female mice with copulatory plugs were selected as recipients for pseudopregnancy for 12 h. The frozen-thawed blastocysts were then transferred into the recipients at 2.5 days of pseudopregnancy.

Tax treatment. Following the blastocyst transfer, the pregnant WT and PTN^{-/-} mice were injected intraperitoneally with either corn oil taxsolution (3 mg/40 g body weight; Sigma; EMD Millipore) or an equal volume of corn oil vehicle solution on day 10 of pregnancy. The tax was injected for 5 days consecutively. This dose regimen has been reported previously (31). Four groups were established in terms of the genotype and treatment: WT corn oil (Wt) (63 mice), WT tax (tax/Wt) (62 mice), PTN^{-/-} corn oil (PTN^{-/-}) (64 mice) and the PTN^{-/-} tax (tax/PTN^{-/-}) (64 mice). Following 19-21 days of blastocyst transfer, the next-generation mice were born. According to the occurrence PE of in mice during pregnancy, the mice in each group were further divided into PE and non-PE mice. Thus, there were 8 groups as follows: WT corn oil, PE/WT corn oil (PE/Wt), WT tax (tax/Wt), PE/WT tax (PE/tax/Wt), PTN^{-/-} corn oil (PTN^{-/-}), PTN^{-/-} corn oil (PE/PTN^{-/-}), the PTN^{-/-} tax (tax/PTN^{-/-}) and PE/PTN^{-/-} tax (PE/tax/PTN^{-/-}).

Enzyme-linked immunosorbent assay (ELISA). The blood samples were collected via venipuncture into tubes containing anticoagulants. The protein level of PTN in serum was determined on covered 96-well ELISA plates, as previously reported (32). Rabbit anti-human PTN monoclonal antibodies (1:2,000, ab14025; Abcam, Cambridge, MA, USA) were diluted in Tris-buffered saline (TBS) and incubated at 4°C overnight. Biotinylated affinity-purified anti-rabbit secondary antibody (1:50,000, ab6720; Abcam) was added into the wells and incubated at room temperature for 1 h. Streptavidin/alkaline phosphatase conjugate (Roche Diagnostics GmbH, Mannheim, Germany) was added and maintained at room temperature. The absorbance at 405 nm was measured on a plate reader. Recombinant human PTN (R&D Systems, Inc.) was used as a standard control. The concentration of TNF-α was also measured using an ELISA kit (ab181421; Abcam) according to the protocols. The kit mainly consists of anti-TNF-α antibodies and the reagent for the ELISA assay. The absorbance of TNF-α was determined at 450 nm.

Blood pressure measurement. The non-invasive tail-cuff method using the CODA™ system (Kent Scientific, Torrington, CT, USA) was applied to monitor the blood pressure of mice following the steps described in a previous study (33). The measurements were all performed 5 min prior to the start of the experiment. The assessments were repeated four times for each measurement.

Measurement of urine protein concentration. The urine was sampled using a bladder massage method, as described previously (34). The quantity of urine protein was determined using a Bradford assay (Bio-Rad Laboratories, Inc., Hercules, CA, USA). Standard solutions were diluted with Bradford reagent, and the mixture of the two was incubated at room temperature for 5 min. The absorbance was read at 595 nm and then

a standard curve was obtained. The urine protein level was assessed according to this curve.

Immunohistochemistry (IHC) and hematoxylin and eosin (H&E) staining. The paraffin-embedded placental and kidney tissues from the pseudopregnant mice were dewaxed and rehydrated. For H&E staining, the sections (4-μm-thick) were stained with hematoxylin at room temperature for 10 min. Following incubation with 1% hydrochloric acid ethanol for 3 sec, the section was stained with 0.5% eosin for 30 sec. For IHC, the sections were preheated in distilled water at 37°C. The sections were first heated at 120°C in citric acid buffer and then maintained at room temperature for 20 min for antigen retrieval. Fetal calf serum (Gibco/Thermo Fisher Scientific, Waltham, MA, USA) in PBS (20%) was incubated with the sections for 10 min. The primary antibody was added onto the sections and maintained at 4°C overnight following removal of the serum. The secondary antibody (biotinylated) (Cell Signaling Technology, Inc.) was incubated for 30 min. Subsequently, peroxidase-conjugated streptavidin biotin (Cell Signaling Technology, Inc.) was added and maintained for 30 min at room temperature. Diaminobenzidine was used to identify the peroxidase activity. Finally, the sections were counterstained with Mayer's hematoxylin (Sangon Biotech Co., Ltd., Shanghai, China). Primary antibodies used in IHC were as follows: Anti-PTN goat polyclonal (1:20, cat. no. ab223674; Abcam), anti-RPTPβ/ζ mouse monoclonal (1:200, cat. no. sc-33664; Santa Cruz Biotechnology, Inc., Dallas, TX, USA), anti-SDC1 rabbit monoclonal (1:2,000, cat. no. ab128936; Abcam) and anti-SDC3 rabbit monoclonal (1:20, ab36653, antibody). The corresponding goat anti-rabbit IgG (ab64256, 1:200) or goat anti-mouse IgG (ab64255, 1:200) secondary antibodies used were all biotinylated and purchased from Abcam.

Western blot analysis. Lysates from the placenta were denatured in boiling water for 5 min. The lysates (25 μg/lane) were mixed with loading buffer and electrophoresed on a 12% SDS PAGE gel. The proteins were then transferred onto PVDF membranes. To block the non-specific proteins, not fatty milk was incubated with the membrane for 2 h at room temperature. Anti-pleiotrophin (1:10,000, cat. no. ab79411; Abcam), anti-RPTPβ/ζ (1:800, cat. no. sc33664; Santa Cruz Biotechnology, Inc.), anti-Syndecan-1 (1:1,000, cat. no. ab181789), anti-SDC3 (1:1,000, cat. no. ab155952) (both from Abcam), anti-anaplastic lymphoma kinase (ALK; cat. no. sc-398791; Santa Cruz Biotechnology, Inc.) and anti-actin antibodies (1:1,000, cat. no. ab8226; Abcam) were used as the primary antibodies. The primary antibodies were incubated with the membranes at 4°C overnight. The appropriate HRP-conjugated IgG secondary antibody (ab6721, 1:2,000; Abcam) was incubated with the membranes at room temperature for 1 h. An ECL system (Amersham; GE Healthcare Life Sciences, Chalfont, UK) was used to detect the bands.

Statistical analysis. Data are shown as the means ± standard deviation (SD) and were analyzed using a two-tailed Student's t-test or one-way analysis of variance followed by Tukey's post hoc test. P<0.05 was considered to indicate a statistically significant difference. GraphPad Prism version 6.0

Results

Clinical outcome results of vitrified-warmed embryo transfer. PE in pregnancies following ART has gained increased attention (35). The clinical characteristics of the patients in the present study are summarized in Table I. It was found that the incidence of PE following vitrified-warmed embryo transfer was 13.5% (12/89). PE is considered to be systematic inflammatory responses. The concentration of TNF- α was determined by ELISA, which is closely associated with inflammation (25). Notably, as shown in Table II, increased secretion of TNF- α was observed in patients with PE than that in normal pregnant women (29 $\pm$ 4 vs. 12 $\pm$ 3 pg/ml, P <0.05). It was also found that the activity of PTN was reduced in patients with PE (6 $\pm$ 13 ng/ml) when compared with the normal patients (8 $\pm$ 17 ng/ml).

Outcome of vitrified-warmed embryo transfer in mice. To investigate the potential influence of PTN on the incidence of PE following vitrified-warmed embryo transfer, the present study evaluated the pregnancy outcome of the conditional induced PTN-deficient mice. As shown in Table III, the knock-down of PTN did not affect the pregnancy rate, which was ~40% among the four groups. However, compared with the PTN^{-/-} group (P <0.05), the birth rate in the tax/PTN^{-/-} group decreased by almost half. In addition, the incidence of PE was significantly increased by the deficiency of PTN compared with that in the PTN^{-/-} group (P <0.05).

Figure 1. (A) Blood pressure at BG and at different periods following embryo transfer in mice with or without PE. (B) Urine protein levels at BG and at different periods following embryo transfer in mice with or without PE determined using a Bradford assay; * P <0.05 vs. PE/Wt; $^{\#}P$ <0.05 vs. PE/tax/Wt; $^{\&}P$ <0.05 vs. PE/PTN^{-/-}. At least eight mice were included. PE, preeclampsia; BG, before gestation; Wt, wild-type; tax, tamoxifen; PTN, pleiotrophin.

As increased hypertension and urine protein content are two principal features of PE, the present study monitored the change of blood pressure and the content of urine protein in mice prior to and following their pregnancies at certain stages. These two parameters in control mice (non-PE mice) were maintained at a normal level throughout the study. As shown in Fig. 1, the blood pressure of the PE mice remained stable prior to pregnancy and in early pregnancy (during the first 13 days of pregnancy). At day 15 of pregnancy, a significant increase in blood pressure was observed in these PE mice. In addition, the blood pressure in those PE mice that lacked PTN was higher than that in the other PE mice (PE/Wt. vs. PE/tax/PTN^{-/-} at 15 days: 105 $\pm$ 5.0 vs. 112 $\pm$ 4.8 mmHg, P <0.05). Additionally, the protein content of urine in the PE mice began to increase from day 13 of pregnancy, and was higher in the PE mice that lacked PTN than in the other mice with PE (Wt vs. tax/PTN^{-/-} at 13 days: 0.51 $\pm$ 0.05 vs. 0.565 $\pm$ 0.038 mg/day, P <0.05). From day 19 of pregnancy, the blood pressure and the urine protein content reached the highest levels in the PE mice that lacked PTN.

Concentrations of TNF- α and PTN in mice. To determine the effect of PTN on PE following vitrified-warmed embryo transfer, the activities of PTN and TNF- α were identified in mice. As shown in Fig. 2A, the release of PTN was reduced in the PE mice as pregnancy progressed, and the release of PTN was higher in the PE mice that lacked PTN than in the other mice with PE. The secretion of TNF- α showed an increasing trend in the PE mice as pregnancy progressed. The level of PTN was low in the PE mice that lacked PTN compared with the other mice with PE, and the content of TNF- α was highest in the PE mice that lacked PTN (Fig. 2B).

Table III. Outcomes of vitrified-warmed embryo transfer in mice.

Factor	Wt	tax/Wt	PTN ^{-/-}	tax/PTN ^{-/-}
Animals (n)	152	152	156	155

Expression of PTN and its receptors in placental tissue. PTN is involved in inflammation via its distinct receptors (36). The present study compared the expression level of PTN and its receptors in the placenta of PE and normal mice. As shown in Fig. 3, the expression levels of PTN, SDC1, SDC3 and RPTPβ/ζ were reduced in the PE mice when compared with levels in the normal mice, whereas the expression level of ALK was similar among the groups. It appears that the expression levels of SDC1 and SDC3 were not affected significantly by the knockdown of PTN, whereas the expression of RPTPβ/ζ appeared to be suppressed by the knockdown of PTN. In order to determine whether PTN and its receptors are involved in PE following vitrified-warmed embryo transfer, the expression pattern of PTN and its receptors in each group were determined by IHC (n=4). Staining for the expression of PTN was present in the cytoplasm and mesenchyme (ME) in the placenta of control mice, whereas

perinuclear and ME staining was weaker in the placenta of PE mice (Fig. 4). The PTN staining faded out in mice that lacked PTN, although PTN staining remained present in the tax/PTN^{-/-} mice as the efficiency of the conditional knockout was not 100% effective (negative staining for the isotype control of PTN; data not shown). The expression of PTN was almost absent in the tax/PTN^{-/-}PE mice (Fig. 4D). In the placental tissues of the control mice, strong fetal macrophage (FM) staining for SDC1 was also observed. Fainter staining was observed in the ME and fetal vessels (FV). In the PE mice, not all FMs were stained and other staining had almost disappeared (Fig. 5). The expression of SDC1 appeared to be reduced in the PTN-knockout mice (Fig. 5D). Strong diffuse cytoplasmic staining for RPTPβ/ζ was also noted. Intensive staining in the ME, villous cytotrophoblasts, syncytiotrophoblasts and FMs were observed in the control mice. However, this staining was weaker or absent in the placenta of the PE mice (Fig. 6).

Kidney injury in mice. Renal damage is often connected to PE (37). Therefore, the present study examined kidney injury in the mice. As shown in Fig. 7, the glomeruli, renal capsule and tubular structures were clear in the kidneys of the control mice. However, the Bowman's capsule and the opening of capillary loops were reduced, and inflammatory cell infiltration increased in the PE mice. In addition, kidney injury was more severe in the PTN-knockout PE mice.

Discussion

The risk of PE in pregnancies following ART is high (38). PE is a maternal complication accompanied with high blood pressure and an increase of urine protein during pregnancy. The incidence of PE is 5-8% worldwide (39,40). The present study analyzed the outcome of clinical pregnancy following embryo transfer. The results showed that the incidence of PE was higher (12%) in mice conceiving through vitrified-thawed embryo transfer. Therefore, it is of medical importance to further investigate the molecular mechanism of PE.

PE is considered to be a type of systemic inflammatory responses. Poor placentation and endothelial disorder are two critical stages of PE (24). Heparin-binding growth factors, including PTN, have been reported to be altered in PE. PTN is distributed in the placenta and is important to placentation and inflammation via its receptors. The results of the present study showed that the concentrations of TNF-α and

PTN were increased and decreased, in pregnant women with PE, compared with those in non-PE women, respectively. The enhanced secretion of TNF-α was in accordance with a previous study (41). In addition, to a certain extent, the decreased PTN suggested its potential role in PE. However, less is known regarding the role of PTN on the incidence of PE following embryo transfer. Therefore, the present study focused on whether and how PTN knockout affects the risk of PE following vitrified-thawed embryo transfer.

Compared with the wild-type group, the present study found that the risk of PE in PTN^{-/-} mice was increased following treatment with tax. In addition, the blood pressure and urine protein content were increased in PE mice as time progressed, and these reached the highest levels on day 19 of pregnancy. Furthermore, the blood pressure and urine protein content were higher in the PE mice treated with tax than that in the other PE mice. In addition, the level of PTN increased as pregnancy progressed in the non-PE mice, but declined in

Figure 5. Immunohistochemistry for the expression pattern of RPTPβ/ζ in the placenta of the (A) Wt group (arrows indicate ME, VT and ST), (B) tax/Wt group (arrows indicate FM, VT and ST), (C) PTN^{-/-} group (arrows indicate ST), and (D) tax/PTN^{-/-} group (arrows indicate the ME). The experiments were repeated at least three times independently. PE, preeclampsia; Wt, wild-type; tax, tamoxifen; PTN, pleiotrophin; RPTPβ/ζ, receptor protein tyrosine phosphatase β/ζ; ME, mesenchyme; VT, villous cytotrophoblast; ST, syncytiotrophoblast; FM, fetal macrophage. the PE mice. By contrast, the level of TNF-α remained at a steady level in the non-PE mice, but increased in the PE mice as pregnancy progressed. Similar to blood pressure and urine protein content, the activity of TNF-α was higher in the PE mice treated with tax than that in the other PE mice. These results indicated that the reduction of PTN increased the risk of PE following vitrified-thawed embryo transfer.

The function of PTN is largely dependent on its receptors (42). To further examine the role of PTN in the occurrence of PE, western blot analysis was performed to determine the expression of PTN and its receptors, including SDC1, SDC3, RPTPβ/ζ and ALK, in the placenta. The data showed that the expression of RPTPβ/ζ was reduced in PE mice treated with tax, compared with that in mice treated with corn oil, and that the expression levels of SDC1 and SDC3 were marginally suppressed in the PE mice treated with tax. As a low expression of SDC1 has been demonstrated to promote PE (43), IHC was used to identify the expression pattern of PTN, RPTPβ/ζ and SDC1 in the placenta. The results showed that the staining for PTN was perinuclear, and was also observed in FMs and ME, which was in line with a previous study (26). These results confirmed the pro-angiogenic effect of PTN in these sites (44). The receptors SDC1 and RPTPβ/ζ shared certain overlapping expression patterns as PTN. These results were partly in line with a previous study (26). In the present study, the finding that the staining of

PTN in the syncytial microvillous membrane was adjacent to areas of completely unstained membrane was recorded, and this suggested its variation in the membrane (45). However, the expression of PTN and its receptors was weaker in the PE mice. Notably, the expression levels of SDC1 and RPTPβ/ζ were reduced in PE conditions, with no changes in PE mice with or without tax treatment. Although this result was not in accordance with the results from the western blot analysis, the possibility that the receptors of PTN may be associated with the incidence of PE following embryo transfer cannot be excluded. Further investigations are required to examine the role of its receptors in more detail. In addition, the present study observed that the kidney injury caused by PE was increased by the knockout of PTN. Therefore, these results indicated that the reduced activity of PTN was associated with PE following embryo transfer.

To the best of our knowledge, the present study provides the first comprehensive investigation of the potential role of PTN in PE following vitrified-thawed embryo transfer. However, the underlying mechanisms remain to be fully elucidated. The results showed that PTN may be relevant to the inflammatory response in PE, however, as a heparin-binding factor, PTN may affect the balance of the clotting/anticoagulant system via heparin, affecting the homeostasis of the clotting/anticoagulant in PE. In addition, PTN and its receptor have been reported to be involved in the metabolism of catecholamines,

Figure 6. Immunohistochemistry for the expression pattern of SDC1 in the placenta. Expression of SDC1 in the (A) Wt group (arrows indicate FM and ME), (B) tax/Wt group (arrows indicate FM), (C) PTN^{-/-} group (arrows indicate FM), and (D) tax/PTN^{-/-} group (arrows indicate FM and FV). The experiments were repeated at least three times independently. PE, preeclampsia; Wt, wild-type; tax, tamoxifen; PTN, pleiotrophin; SDC1, syndecan-1; ME, mesenchyme, FM, fetal macrophage; FV, fetal vessel. Magnification, x100 for the upper row and x200 for the lower row.

Figure 7. Hematoxylin and eosin staining of kidney tissues. (A) Wt group, (B) tax/Wt group, (C) PTN^{-/-} group, (D) tax/PTN^{-/-} group. The experiments were repeated at least three times independently. PE, preeclampsia; Wt, wild-type; tax, tamoxifen; PTN, pleiotrophin. Magnification, x200.

and thereby regulate oxidative stress in PE (26,46). Therefore, further investigation of the role of PTN and its receptors on PE following ART are required.

In conclusion, the risk of PE was shown to increase following vitrified-thawed embryo transfer; the knockout of PTN enhanced the incidence and symptoms of PE in pregnant

mice following embryo transfer. In addition, the inflammatory response was more marked in PE mice that lacked PTN than that in other PE mice. The expression of PTN and its receptors reflected their possible role in PE. The present study suggested a potential direction for the detailed investigation of PTN in PE following embryo transfer.

Funding

This study was supported by the Henan Provincial Science and Technology Project (grant no. 201602359).

Availability of data and materials

All data generated or analyzed during this study are included in this published article.

Authors' contributions

SL wrote the main manuscript and analyzed the data. FW performed the experiments. GL conceived and designed the study. All authors have read and approved the final manuscript.

Ethics approval and consent to participate

All protocols associated with humans in the present study were approved by the Review Board of Luoyang Central Hospital Affiliated to Zhengzhou University. All participants provided permission to cooperate to undertake the relevant study and provided written informed consent. Animal experiments were performed with the approval of the Animal Ethics Committee of Luoyang Central Hospital Affiliated to Zhengzhou University.

Patient consent for publication

Not applicable.
