Abstract. The inflammatory response is important in the pathogenesis of myocardial ischemia/reperfusion (I/R) injury. Picroside II, the primary active constituent of Picrorhizae, has been reported to protect the myocardium from I/R-induced injury, however, the exact mechanism underlying these protective effects remains unclear. The aim of the present study was to investigate the mechanism underlying the protective effects of picroside II on I/R-induced myocardial injury. Adult male Sprague-Dawley rats underwent 1 h left coronary artery occlusion followed by 3 h reperfusion. Picroside II was administered (10 mg/kg) via the tail vein 30 min prior to left coronary artery occlusion. The results revealed that pretreatment of picroside II could significantly alleviate I/R-induced myocardial injury concomitantly with a decrease in inflammatory factor production. In addition, picroside II was also able to decrease high mobility group box 1 (HMGB1) expression, and release and downregulate the expression of the receptor for advanced glycation end products (RAGE), toll-like receptor (TLR)-2 and TLR-4. Furthermore, picroside II was able to inhibit nuclear factor- κ B (NF- κ B) activation. The

results indicated that the protective effect of picroside II on I/R-induced myocardial injury was associated, at least partly, with inhibition of the inflammatory response by suppressing the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B signaling pathway.

Introduction

Myocardial ischemia/reperfusion (I/R) is a pathological condition, which is characterized by an initial restriction of the blood supply to the myocardium followed by the subsequent restoration of perfusion (1). Although reperfusion is the most effective treatment used to rescue ischemic myocardium, reperfusion may paradoxically lead to severe or additional myocardial injury. Myocardial I/R injury is a common problem in clinical practice and may result in serious consequences. The exact pathophysiology mechanism underlying myocardial I/R injury is complicated and has yet to be fully understood. However, numerous studies support that the inflammatory response is important in the pathogenesis of myocardial I/R injury (2,3) due to the inhibition of inflammation significantly attenuating I/R-induced myocardial injury (4,5). There is increasing evidence to suggest that the inflammatory response during myocardial I/R is closely associated with high mobility group box 1 (HMGB1) (6,7).

HMGB1 is a non-chromosomal nuclear protein that may be actively secreted from activated immune cells or passively released from necrotic and apoptotic cells (8). Numerous studies demonstrated that extracellular HMGB1 is a potent pro-inflammatory mediator (9,10), and is important in triggering the inflammatory response during myocardial I/R (11,12). Furthermore, it has been reported that HMGB1 exerts its pro-inflammatory effects via its specific receptors, which mainly include a receptor for advanced glycation end products (RAGE), Toll-like receptor (TLR)-2 and TLR-4 (13). The interaction of HMGB1 and its specific receptors activates nuclear factor- κ B (NF- κ B), and ultimately leads to increased expression and

Key words: picroside II, myocardial ischemia/reperfusion injury, inflammation, high mobility group box 1

release of numerous inflammatory factors (14). Thus, the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B pathway is an important inflammatory signaling pathway (13).

Picroside II is a primary active constituent of traditional Chinese medicine. Picrorhizae has been extensively used in China to treat numerous diseases, including upper respiratory tract diseases, disorder of the liver, dyspepsia and chronic diarrhea (15). Previously, it has been reported that picroside II has anti-inflammatory properties and exerts beneficial effects in the nervous and urinary systems. In the rat model of middle cerebral artery occlusion and reperfusion, pretreatment with picroside II could significantly improve the neurobehavioral function and inhibit neurocyte apoptosis, which was correlated with a decrease of inflammatory factor production by inhibition of the TLR-4/NF- κ B signaling pathway (15). In addition, the study by Wang *et al* (16) demonstrated that picroside II was able to decrease I/R-induced renal fibrosis in rats by inhibition of long-term inflammation. Recently, it has been reported that picroside II has a protective effect on myocardial I/R injury in rats (17). Furthermore, our previous investigation also demonstrated that picroside II was able to inhibit hypoxia/reoxygenation (H/R)-induced cardiomyocyte apoptosis (18); however, the exact mechanism underlying the cardioprotective effects of picroside II in myocardial I/R injury is not fully understood.

Due to inflammation being important in myocardial I/R injury, picroside II having anti-inflammatory properties, and the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B pathway being an important inflammatory signaling pathway, the present study aimed to explore whether the protective effect of picroside II on myocardial I/R injury in rats is associated with suppressing the inflammatory response by inhibition of the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B signaling pathway.

Materials and methods

Animals. Male Sprague-Dawley rats (age, 8 weeks; weight, 250–300 g) were obtained from the Experimental Animal Center of Central South University (Changsha, China). All rats were housed in standard laboratory conditions in an air conditioned room at temperature $24\pm1^{\circ}\text{C}$, with a 12 h light/dark cycle with a relative humidity of 50–60%. All rats had free access to food and water. The study was performed in accordance with the NIH Guide for the Care and Use of Laboratory Animals and was approved by the Central South University Veterinary Medicine Animal Care and Use Committee. The present study was approved by the ethical committee of Ruikang Hospital Affiliated to Guangxi University of Chinese Medicine (Nanning, China).

Experimental protocols. The rats were randomly divided into 3 groups ($n=8$ in each group): Group 1, sham-operated control (sham), in which the rats were subjected to surgical manipulation without myocardial ischemia; Group 2, the I/R group, in which the rats were subjected to myocardial ischemia for 1 h followed by reperfusion for 3 h; and Group 3, the picroside II + I/R group, in which the rats were administered 10 mg/kg picroside II dissolved in sterile saline via the tail vein 30 min prior to left coronary artery occlusion. The model of myocardial I/R was established according to a previously

reported method by Li *et al* (19). Briefly, rats were anesthetized by an intraperitoneal injection of 45 mg/kg sodium pentobarbital (Shanghai West Tang Bio-Tech Co., Ltd., Shanghai, China) and then placed in the supine position. The body temperature was maintained at 37°C by an electric heating pad. The trachea was cannulated for artificial ventilation at a rate of 55 breaths/min using a volume-controlled rodent respirator, and the lead-II of the electrocardiogram was monitored with subcutaneous stainless steel electrodes. The chest was opened through a thoracotomy in the left 4 intercostal spaces. After the pericardium was incised, the anterior wall of the ventricle was exposed, a 4/0 silk suture was attached to a small curved needle and was placed around the left coronary artery close to its origin. The complete occlusion of the coronary artery was confirmed by an ST segment elevation in lead-II and from the change of the ventricular color (from red to white). After a 1-h occlusion, the rats underwent 3-h reperfusion. The reperfusion was verified by the return of color in the ischemic area. Sham rats underwent a similar operation with the exception of the coronary artery ligation.

Reagents. Picroside II (purity $>99\%$) was purchased from the Chinese National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). 2,3,5-triphenyltetrazolium chloride (TTC) was obtained from Sigma-Aldrich (St. Louis, MO, USA). The creatine kinase (CK) and lactate dehydrogenase (LDH) assay kits were purchased from Nanjing Jiancheng Bioengineering Institute (Nanjing, China). The terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) kit was from Roche (Indianapolis, IN, USA). The antibodies targeting HMGB1, RAGE, TLR-2, TLR-4 and β -actin were purchased from Abcam (Cambridge, UK). TRIzol reagent was a product of Invitrogen (Thermo Fisher Scientific, Inc., Waltham, MA, USA). The First Strand cDNA Synthesis kit was obtained from MBI Fermentas, Inc. (Vilnius, Lithuania) and the ELISA kits of TNF- α , IL-6, IL-1 β , intercellular adhesion molecule-1 (ICAM-1), HMGB1 and NF- κ B p65 were purchased from Shanghai Jiang Lai Biotechnology Co., Ltd. (Shanghai, China).

Assessment of myocardial injury

Histological evaluation. The morphological changes of the cardiac tissue were evaluated by hematoxylin and eosin staining. Briefly, following 3-h reperfusion, the rats were sacrificed with an overdose of sodium pentobarbital (220 mg/kg; i.p. injection) and their hearts were harvested. Following the removal of the fatty tissues, the atria and right ventricle, and the remaining left ventricle was fixed in 4% paraformaldehyde and prior to embedding in paraffin. The paraffin-embedded tissue was sliced into 5 μm thick sections, and the sections were then stained with hematoxylin and eosin according to standard protocol (20). The morphological changes to the cardiac tissue were observed under a light microscope (Leica DM4000B; Leica Microsystems GmbH, Wetzlar, Germany).

CK and LDH activity assay. To assess myocardial injury, the activity of CK and LDH was determined. Briefly, after 3-h reperfusion, the blood samples were collected from the carotid artery, and then centrifuged at $1,000 \times g$ for 20 min at 4°C . The activity of CK and LDH was detected using the commer-

cially available colorimetric assay kits (Nanjing Jiancheng Bioengineering Institute, Nanjing, China). in accordance with the manufacturer's instructions.

Infarct size. The infarct size was measured by TTC staining. Briefly, after 3-h reperfusion the left coronary artery was occluded again at the original site, and 1 ml Evans blue dye (2%) was injected via the femoral vein. The risk area was analyzed using negative staining with Evans blue. Next, the rat was sacrificed with an overdose of sodium pentobarbital (220 mg/kg; i.p. injection) and the entire heart was rapidly excised. Following the removal of the fatty tissues, atria and right ventricle, the remaining left ventricle was frozen at -80°C. The frozen left ventricle was cut transversely into 5 sections (~2 mm) and the risk area was separated from the colored non-ischemic area (blue). Furthermore, the sections were incubated in 1% TTC at 37°C for 15 min, and the infarcted myocardium was stained white, whereas the viable myocardium was stained red. The infarct and the risk area were analyzed using an image analyzer (version 6.0; Media Cybernetics Inc., Rockville, MD, USA), and the infarct size was expressed as a percentage of the risk area volume (% infarct size/risk area).

Apoptosis analysis. Cardiomyocyte apoptosis was analyzed by TUNEL staining. Briefly, at the end of 3 h reperfusion, the heart was removed and washed in phosphate-buffered saline. The anterior wall tissues of the left ventricle were fixed in 4% paraformaldehyde and embedded in paraffin. The paraffin-embedded cardiac tissues were then cut with a thickness of 5 μ m, and the sections were then stained using a TUNEL kit following the manufacturer's instructions. The number of TUNEL-positive cardiomyocytes was visualized under a light microscope, and the apoptosis percentage was expressed as a ratio of apoptotic cells to total cardiomyocytes per field.

ELISA. Following reperfusion for 3 h, the blood samples were collected and centrifuged 1,000 \times g for 20 min at 4°C, and the serum samples were stored at -80°C until further analysis. The concentrations of TNF- α (cat. no. JL13202), IL-6 (cat. no. JL15538), IL-1 β (cat. no. JL15543), ICAM-1 (cat. no. JL15530) and HMGB1 (cat. no. JL13892) in the serum and NF- κ B p65 (cat. no. JL10501) in nuclear lysates of the myocardium were detected using commercially available ELISA kits (Shanghai Jiang Lai Biotechnology Co., Ltd., Shanghai, China) in accordance with the manufacturer's instructions.

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) analysis. A 100 mg myocardial tissue sample was collected from each rat for RNA isolation. A mortar and pestle, along with liquid nitrogen, were used for disruption of samples. Homogenization of each sample was completed by using a syringe and needle. Total RNA was extracted from 100 mg myocardium using TRIzol reagent (Invitrogen; Thermo Fisher Scientific, Inc.), and the concentration was determined by a spectrophotometric absorbance measurement at 260 nm. A 1 μ g RNA aliquot was converted into cDNA using the M-MLV reverse transcriptase kit (Promega Corporation, Madison, WI, USA), and the cDNA was then used for qPCR. Quantitative analysis of the mRNA

expression was performed using the ABI 7300 quantitative PCR system (Thermo Fisher Scientific, Inc.) with the Power SYBR-Green PCR Master Mix kit. PCR primers (synthesized by Sangon Biotech Co., Ltd., Shanghai, China) were as follows: HMGB1 (forward, 5'-ATGGGCAAAGGA GATCCTA-3' and reverse, 5'-ATTCATCATCATCATCTT CT-3'); RAGE (forward, 5'-TCTCAGAAGCCCAAGGAA GAGT-3' and reverse, 5'-CCTAGGTCTGAAGGCCCTGAG T-3'); TLR-2 (forward, 5'-ACGCAGTGAGTGGTGCAAGTA T-3' and reverse, 5'-CTTCTTCAATGGGTTCCAGCAA-3'); TLR-4 (forward, 5'-GGCATCATCTTCATTGTCTTG and reverse, 5'-AGCATTGTCCTCCCACTCG-3') and β -actin (forward, 5'-AGGGAAATCGTGCGTGAC-3' and reverse, 5'-CGCTCATTGCCGATAGTG-3'). The PCR amplification profiles consisted of denaturation at 95°C for 10 min, followed by 40 cycles of denaturation at 95°C for 15 sec and annealing at 60°C for 60 sec. In addition, the relative expression values were normalized to the expression value of β -actin using the $2^{-\Delta\Delta C_q}$ method (21). All amplification reaction for each sample was performed four times.

Western blot analysis. Myocardial proteins were extracted using the Tissue Total Protein Extraction kit (Beyotime Institute of Biotechnology, Jiangsu, China). Nuclear proteins were isolated using a Nuclear Extraction kit (Beyotime Institute of Biotechnology) in accordance with the manufacturer's instructions. The protein concentration was quantified by a Bradford protein assay (Beyotime Institute of Biotechnology). Equal amounts of protein (40 μ g from each group) were loaded onto a 10% sodium dodecyl sulfate-polyacrylamide gel, and then transferred onto a polyvinylidene fluoride membrane. Following blocking for 1 h with 5% skimmed milk at room temperature, the membranes were incubated with the primary antibody for HMGB1 (rabbit polyclonal antibody; diluted 1 μ g/ml (1:1,000; cat. no. ab191583), RAGE (rabbit polyclonal antibody; 1:1,000; cat. no. ab37647), TLR-2 (rabbit monoclonal antibody; 1:5,000; cat. no. ab108998), TLR-4 (mouse monoclonal antibody; 1:5,000; cat. no. ab30667) and β -actin (rabbit polyclonal antibody; 1:1,000; cat. no. ab1801) overnight at 4°C, followed by incubation with the corresponding horseradish-conjugated secondary antibody (goat anti-rabbit; 1:10,000; cat. no. ab175773 or goat anti-mouse; 1:10,000; cat. no. ab97040) for 1 h at room temperature. The protein bands were quantified using scanning densitometry, and the results were normalized to the expression of β -actin.

Statistical analysis. SPSS statistical software was used for statistical analysis (version 18.0; SPSS, Inc., Chicago, IL, USA) Data are expressed as the mean \pm standard error of the mean. All the values were analyzed using analysis of variance and the Newman-Keuls Student's t-test. $P < 0.05$ was considered to indicate a statistically significant difference.

Results

Effect of picoside II on I/R-induced myocardial injury. As shown in Fig. 1A, myocardial infarction was not observed in the sham group. In the I/R group, the infarct size was $52.95 \pm 3.98\%$ following ischemia for 1 h and reperfusion for

Figure 1. Effect of picroside II on I/R-induced myocardial injury in rats (n=8 in each group). (A) Infarct size (expressed as the percentage of the area at risk). (B) Representative image of hematoxylin and eosin staining. (C) CK and LDH activity. **P<0.01, vs. Sham; #P<0.05 and ##P<0.01, vs. I/R. I/R, ischemia/reperfusion; CK, creatine kinase; LDH, lactate dehydrogenase.

3 h. Hematoxylin and eosin staining revealed that the structure of the myocardium in the sham group was arranged regularly, and the cell boundary was clear. Compared with the sham group, the myocardial structure in the I/R group presented irregularity, with some of cells shrinking and getting distorted or ruptured. There was marked inflammatory cell infiltration in the myocardial intercellular space (indicated by the arrows; Fig. 1B). Consistent with the above results, the activity of CK and LDH that were used as indicators of myocardial injury were markedly increased following ischemia for 1 h and reperfusion for 3 h (Fig. 1C). However, pretreatment of picroside II could markedly inhibit these effects induced by myocardial I/R (Fig. 1).

Effect of picroside II on I/R-induced cardiomyocyte apoptosis. TUNEL staining revealed that the percentage of apoptotic cells was remarkably increased following ischemia for 1 h and reperfusion for 3 h compared with the sham group. However, this effect induced by I/R was significantly ameliorated by administration of picroside II (Fig. 2).

Effect of picroside II on I/R-induced inflammatory factor production. Following ischemia for 1 h and reperfusion for 3 h, the concentration of TNF- α , IL-6, IL-1 β and ICAM-1 were remarkably increased compared with the sham group. However, this effect induced by I/R was significantly attenuated by pretreatment of picroside II (Fig. 3).

Effect of picroside II on I/R-induced HMGB1 expression and release. qPCR and western blotting analysis demonstrated that the HMGB1 mRNA and protein expression were significantly upregulated in the I/R group compared with that in the sham group. Consistent with these results, the concentration of HMGB1 in the serum was also significantly increased in the I/R group. However, the increased expression and concentration of HMGB1 were significantly attenuated by pretreatment with picroside II (Fig. 4).

Effect of picroside II on I/R-induced HMGB1 receptor expression. qPCR analysis demonstrated that the mRNA expression of RAGE, TLR-2 and TLR-4 was markedly upregulated after isch-

emia for 1 h and reperfusion for 3 h. Consistent with the mRNA expression, the protein expression of RAGE, TLR-2 and TLR-4 was also significantly increased in the I/R group. However, the increased expression of mRNA and protein was remarkably downregulated by pretreatment of picoside II (Fig. 5).

Effect of picoside II on I/R-induced NF-κB activation. Since the activation of NF-κB is necessary to inflammatory factor production, the NF-κB activity was investigated in the present study. Following ischemia for 1 h and reperfusion for 3 h, the NF-κB activity was increased, as indicated by the increased optical density of NF-κB p65 in the nuclear lysates. However, this effect induced by I/R was significantly inhibited by administration of picoside II (Fig. 6).

Discussion

In the present study, a protective effect of picoside II on I/R-induced myocardial injury was identified, which was indicated by ameliorating myocardial morphology and decreasing infarct size, cardiomyocyte apoptosis and the activity of CK and LDH. The results also demonstrated that pretreatment with picoside II was able to decrease I/R-induced inflammatory factor production, inhibit HMGB1 expression and release, downregulate RAGE, TLR-2 and TLR-4 expression, and decrease NF-κB activity.

Myocardial I/R injury is a common problem following coronary artery bypass graft, heart transplantation and acute coronary syndrome amongst other problems (22). Although

ischemic heart disease is one of the main reasons for morbidity and mortality worldwide, the exact pathophysiological mechanism underlying myocardial I/R injury is not fully understood. Currently, it is well-recognized that the inflammatory response is one of the primary mechanisms underlying myocardial I/R injury (2,3). Myocardial I/R may cause local sterile inflammation and produce numerous inflammatory factors, including TNF- α , IL-6, IL-1 β and ICAM-1 amongst others (23). In addition, myocardial injury is thought to be a result of an intensive inflammatory response initiated by the infiltration of leukocytes and the production of inflammatory factors (22). Infiltrating cells, particularly neutrophils, are directly toxic to the myocardium by releasing proteases and occluding the microvasculature (24). Excessive production of inflammatory factors damages the myocardium not only by triggering deleterious responses but also by amplifying ongoing responses to build a cascade of injury (25). This cascade refers to the excessive production of inflammatory factors could cause vascular endothelial cell damage and increase vascular permeability, and further activate inflammatory cells that increase the inflammatory response (26). Numerous studies have demonstrated that inhibition of the inflammatory response could markedly suppress myocardial injury induced by I/R in various animal models (27-29). Therefore, decrease in inflammation may be a potential therapeutic strategy for myocardial I/R injury.

Recently, numerous studies suggested that the inflammatory response during myocardial I/R injury is closely associated with HMGB1 (6,7). HMGB1 is a single peptide chain consisting of 215 amino acid residues with a molecular weight of ~30 kDa (30). It is an evolutionarily conserved nuclear protein in all mammals and is expressed in virtually all types of cells (31). Besides exerting its function in the nucleus, extracellular HMGB1 can mediate various physical or pathological processes, including stimulating inflammatory factor expression and release mainly by binding to its specific receptors, such as RAGE, TLR-2 and TLR-4 (32). Therefore, HMGB1 has been recognized as an important pro-inflammatory mediator and is important in initiating and amplifying the

inflammatory response (9-12). In addition, it has been reported that the HMGB1-triggered inflammatory response is crucial in myocardial I/R injury since a decrease in HMGB1 expression and release could significantly inhibit the inflammatory response and ameliorate I/R-induced myocardial injury (11,33). Therefore, inhibition of the HMGB1-mediated inflammatory signaling pathway may be a promising therapeutic strategy for myocardial I/R injury.

Picroside II is an iridoid glucoside isolated from *Picrorhiza scrophulariiflora* Pennell, which has been reported to possess a wide range of pharmacological properties, including anti-oxidative, anti-apoptotic and liver protective effects amongst others (34-36). Furthermore, it has been reported that picroside II is capable of protecting the heart or kidney from I/R-induced injury by inhibition of the inflammatory response (15,16). These studies suggested that picroside II has an anti-inflammation property. Furthermore, studies from our laboratory (Central South University, Changsha, China) and others have demonstrated that picroside II has a protective effect on H/R- or I/R-induced cardiomyocyte injury (17,18), however, the exact mechanism remains unclear. Due to the important role of the inflammatory response in the pathogenesis of myocardial I/R injury and the anti-inflammatory property of picroside II, we hypothesize that the protective mechanism of picroside II on myocardial I/R injury may be associated with the inhibition of the inflammatory response. In the present study, pretreatment with picroside II was observed to inhibit I/R-induced myocardial injury concomitantly by decreasing the inflammatory factor production. As mentioned above, the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B signaling pathway is important and the HMGB1-triggered inflammatory response is crucial in myocardial I/R injury. The present study presumes that the anti-inflammatory effect of picroside II may be associated with the suppression of the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B signaling pathway. A further study demonstrated that picroside II significantly inhibited I/R-induced inflammatory factor production concomitantly with a decreased HMGB1 expression and release, downregulated expression of RAGE, TLR-2 and TLR-4, and decreased NF- κ B activity. These results were concordant with our previously mentioned hypothesis.

In summary, the present study suggested that pretreatment with picroside II was able to protect the myocardium from I/R-induced injury. This beneficial effect was associated, at least partly, with inhibition of the inflammatory response by suppressing the HMGB1-RAGE/TLR-2/TLR-4-NF- κ B signaling pathway. The present study provides a theoretical basis regarding the protective effect of picroside II on myocardial ischemia/reperfusion injury, and also serves as a foundation for the development of novel therapies to be used in cases of ischemic heart disease.
