Abstract. The aim of the present study was to investigate the effect and the underlying mechanism of the combined treatment of rhynchophylla total alkaloids (RTA) and sinapine thiocyanate for protection against a prothrombotic state (PTS) associated with the tumor necrosis factor- α (TNF- α)-induced inflammatory injury of vascular endothelial cells (VECs). A TNF- α -induced VEC inflammatory injury model was established, and cell morphology of VECs was evaluated using scanning electron microscopy. In addition, reverse transcription-quantitative polymerase chain reaction and western blot analysis were performed to examine the mRNA and protein expression of coagulation-related factors, including nuclear factor- κ B (NF- κ B), transforming growth factor- β 1 (TGF- β 1), tissue factor (TF), plasminogen activator inhibitor (PAI-1), protease-activation receptors (PAR-1) and protein kinase C (PKC- α) in VECs. Combined treatment with

RTA and sinapine thiocyanate was demonstrated to reduce, to a varying extent, the mRNA and protein expression of NF- κ B, TGF- β 1, TF, PAR-1, PKC- α and PAI-1. Furthermore, combined treatment with RTA and sinapine thiocyanate was able to downregulate the expression of coagulation-related factors in injured VECs, thereby inhibiting the PTS induced by vascular endothelial injury. The underlying mechanism is partially associated with the TF-mediated activation of the thrombin-receptor signaling pathway that suppresses coagulation during inflammation and balances fibrinolysis in order to inhibit fibrin generation and deposition.

Introduction

Prothrombotic state (PTS) is a condition in which there is a tendency for thrombosis in the body. A previous study reported that PTS is closely associated with target-organ damage during hypertension (1). Vascular endothelial injury occurring during hypertension is the initiating factor for the development of atherosclerosis and thrombosis (2). Extensive crosstalk occurs between vascular endothelial injury, inflammation, and the coagulation/fibrinolytic system, and the impairment of endothelial function during inflammation is the primary cause for enhanced coagulation (3). Vascular endothelial injury may, to a varying extent, reduce or impair the functions of endothelial cells in regulating coagulation and anticoagulation as well as fibrin generation and fibrinolysis, leading to hypercoagulability of the blood, development of pathological thrombosis, and thereby, inducing thromboembolic disease. Therefore, protecting endothelial cells from injury, enhancing the roles of endothelial cells in anticoagulation and anti-thrombosis, and reversing the PTS are of great importance in preventing the occurrence and progression of thrombosis or thromboembolic disease.

Uncaria is a medicinal herb typically used in traditional Chinese medicine for the treatment of hypertension, and its active components are the *Uncaria rhynchophylla* total alkaloids (RTA). Modern pharmacological studies have

Abbreviations: RTA, rhynchophylla total alkaloids; VECs, vascular endothelial cells; SEM, scanning electron microscopy; NF- κ B, nuclear factor- κ B; TGF- β 1, transforming growth factor- β 1; TF, tissue factor; PAI-1, plasminogen activator inhibitor; PAR-1, protease-activation receptors; PKC- α , protein kinase C; PTS, prothrombotic state; PCR, polymerase chain reaction

Key words: rhynchophylla total alkaloids, sinapine thiocyanate, vascular endothelial cells, inflammatory damage, prothrombotic state

demonstrated that RTA exerts a variety of pharmacological effects, including reducing blood pressure and anti-arrhythmia, protecting against cerebral hypoxia and ischemia, inhibiting platelet aggregation and thrombosis, improving vascular remodeling, antagonizing the senescence of vascular endothelial cells (VECs), as well as sedative and antiepileptic effects on the central nervous system (4-6). Raphani semen is the dried ripe seed of *Raphanus sativus* L. Recent studies have shown that Raphani semen exhibits a strong antihypertensive effect and its active component is sinapine thiocyanate (7). It was previously demonstrated that combined treatment with RTA and sinapine thiocyanate shows antihypertensive and protective effects on vascular endothelia. Furthermore, the underlying mechanism is associated with inhibition of the secretion of adhesion molecules by VECs and alleviates inflammatory reactions in the vascular wall (7).

However, whether combined treatment with RTA and sinapine thiocyanate is able to affect coagulation-related factors and inhibit the occurrence of a procoagulant state in vascular endothelial injury remains to be clarified and the underlying mechanisms are unclear. To this end, a model for VEC injury induced by tumor necrosis factor- α (TNF- α) was established and indicators were selected for endothelial coagulation/fibrinolysis. VECs treated with valsartan, which exerts an antihypertensive and protective effect on VECs (8), were used as a positive control. Either RTA, sinapine thiocyanate or a combination of the two was used to treat VECs. Following treatment, the cell morphology of VECs injured by TNF- α -induced inflammation was examined and the expression levels of mRNA and proteins of multiple genes were analyzed, including nuclear factor- κ B (NF- κ B), transforming growth factor- β 1 (TGF- β 1), tissue factor (TF), plasminogen activator inhibitor (PAI-1), protease-activation receptors (PAR-1) and protein kinase C- α (PKC- α). The aim of the present study was to investigate the effect of combined treatment with RTA and sinapine thiocyanate in the protection against the procoagulant state during TNF- α -induced VEC injury, and to elucidate its underlying mechanism.

Materials and methods

Cell culture. Ethical approval for the present study was obtained from the Faculty of Medicine and Health Sciences Ethics Committee for Animal Research, Affiliated Hospital of Shandong University of Traditional Chinese Medicine (Jinan, China), and all efforts were made to minimize the potential for pain and distress in animals. VECs were obtained from the thoracic aorta of 12 male suckling mice, which were 3-7 days old and weighed ~10 g (purchased from the Animal Experiment Center of Shandong University of Traditional Chinese Medicine). The mice were housed at 22 \pm 1°C, under 60% humidity and a 12-h light/dark cycle. Purified water and food was supplied by the Animal Experiment Center of Shandong University of Traditional Chinese Medicine. The suckling mice were anesthetized with 10% chloral hydrate (cat. no. 302-17-0; Yangzhou Aoxin Chemical Factory, Yangzhou, China) (0.03 ml/10 g) and the thoracic aorta was extracted. The thoracic aorta was rinsed in sterile PBS repeatedly, cut into 1 mm³ pieces (without any fixing agents or preservatives) and inoculated evenly into the culture flask.

VECs were cultured using a tissue-sticking method in DMEM/F12 medium (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) containing 10% fetal bovine serum (Hangzhou Sijiqing Biological Engineering Materials Co., Ltd., Hangzhou, China) at 37°C in an atmosphere containing 5% CO₂ in a humidified incubator. VECs were subcultured using a trypsin digestion method when they covered >80% of the bottom of the culture bottle. The primary cells were passaged in a ratio of 1:2 or 1:3, and cells from the 4th to 6th generation were used for the study. The suckling mice were euthanized by overdose anesthesia with sodium pentobarbital (Sigma-Aldrich; Merck KGaA, Darmstadt, Germany) (60 mg/kg, intravenously) and exsanguination following tissue collection.

Treatment. Based on a previous study by the present authors (9), the optimal concentrations for TNF- α , dimethylsulfoxide (DMSO), valsartan, RTA and sinapine thiocyanate, were 5 μ g/l, 0.8 ml/l, 80 mg/l, 100 mg/l and 60 mg/l, respectively. Following cell attachment, VECs were incubated with TNF- α (Cell Signaling Technology, Inc., Danvers, MA, USA) and DMEM/F12 medium at 37°C for 6 h to form models for inflammation, and then preincubated for 48 h and synchronized using the serum hunger method (cells were cultured without serum) for 24 h. The VECs obtained were divided into 7 groups (~10⁶ cells/group): i) Normal control (without special treatment); ii) DMSO (exposed to 0.1% DMSO and DMEM/F12); iii) TNF- α (treated with 3 ng/ml TNF- α); iv) valsartan (treated with 80 mg/l valsartan); v) RTA (treated with 200 mg/l RTA); vi) sinapine thiocyanate (treated with 15 mg/l sinapine thiocyanate); and vii) RTA and sinapine thiocyanate (treated with 100 mg/l RTA and 15 mg/l sinapine thiocyanate) group. Each group, except the normal control, was initially incubated with 3 ng/ml TNF- α for 6 h to induce the inflammation process and was subsequently treated with the aforementioned agents for a further 48 h prior to analysis.

Observation of cell morphology. The morphology of VECs was observed using a scanning electron microscope (SEM) as follows: i) The treated cells were fixed in 2.5% glutaraldehyde solution for 24 h; ii) following fixation, cells were washed in 1.2 mol/l phosphate buffer, which was changed thrice within 3 h; iii) cells were subsequently fixed in 1% osmic acid for 1-1.5 h and washed in double-distilled water, which was replaced thrice in 2 h; iv) cells were dehydrated twice at room temperature, using 50, 70, 80, 90 and 100% ethanol, for 20 min at each concentration; v) the ethanol solution was replaced with isoamyl acetate; cells were placed in a critical point drying apparatus (a high-pressure hermetically sealed container) and liquid carbon dioxide was added. The cells were then dried at a critical temperature of 31.8°C and 72.8 atm, sputter-coated with platinum using an IB-5 sputter coater and observed using an SEM and photographed.

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). TRIzol reagent kits (Invitrogen; Thermo Fisher Scientific, Inc.) were used to extract total RNA and reverse transcription kits (TIANScript RT Kit; Beijing Tiangen Biotech Co., Ltd., Beijing, China) were used to produce cDNA. A LightCycler 480 detection system (Roche Diagnostics,

Indianapolis, IN, USA) was used for qPCR with qPCR kits (Light Cycler 480 SYBR-Green I Master; Roche Diagnostics, Indianapolis, IN, USA) with each sample in triplicate (95°C for 35 sec and 60°C for 31 sec, followed by 40 cycles; 95°C for 15 sec, 60°C for 60 sec and 95°C for 15 sec.). PCR primers used were as follows: NF- κ B: 5'-TGGGACGACACCTCTACACA-3' (forward) and 5'-GGCTCAAAGTTCTCCACCAG-3' (reverse); TF: 5'-AGAGCCCAGAAAGCATCA CCAAG-3' (forward) and 5'-AGCCTCCTCGTCTATGCCAAGC-3' (reverse); TGF- β 1: 5'-CATTGCTGTCCCGTG CAGA-3' (forward) and 5'-AGGTAACGCCAGGAATTG TTGCTA-3' (reverse); PAR-1: 5'-CCTATGAGACAGCCA GAATC-3' (forward) and 5'-GCTTCTTGACCTTCATCC-3' (reverse); PKC- α : 5'-GCTCTACGGACTTATCCACCA-3' (forward) and 5'-TCTGTGACCTCTGCC TTC AG-3' (reverse); PAI-1: 5'-AGGCCCCAGCAGAGTGGAGG-3' (forward) and 5'-GGCGATGCAAGAGGTGCCCA-3' (reverse); β -actin: 5'-CGTTGACATCCGTAAAGA-3' (forward) and 5'-AGCCACCATCCACACAG-3' (reverse). Results were analyzed using the $2^{-\Delta\Delta C_q}$ method (10). Relative expression was normalized against that of β -actin.

Western blot analysis. The cell lysate was prepared using radioimmunoprecipitation lysis buffer (Beijing Solarbio Science & Technology Co., Ltd., Beijing, China) and enzyme inhibitor 4:1. The cells were centrifuged at 8,900 \times g at 4°C for 30 min, and the supernatant was stored at -80°C. Protein concentrations were measured using a bicinchoninic acid assay kit (Beyotime Institute of Biotechnology, Haimen, China). Protein samples (40 μ g total) were separated by SDS-PAGE (12%) and then transferred onto polyvinylidene fluoride membranes (EMD Millipore, Billerica, MA, USA). The membranes were placed in 5% skimmed milk with appropriate primary antibodies and incubated overnight at 4°C. Subsequently, horseradish peroxidase-conjugated secondary antibodies (Beijing Zhongshan Golden Bridge Biotechnology Co., Ltd., Beijing, China) were added and incubated at room temperature for 1 h. An equivalent volume mixture of Immobilon Western (EMD Millipore) was added to the membranes, which were then photographed using a LAS-4000 imager. Image-Pro Plus 4.5 software (Media Cybernetics, Inc., Silver Spring, MD, USA) was used for semi-quantitative image analysis and integrated optical density determination, where the average density was considered as the expression level of the protein. The primary antibodies used were anti- β -actin (bs-0061R; 1:1,500) from Bioss (Beijing Biosynthesis Biotechnology Co., Beijing, China), and anti-PKC- α (ab4124; 1:250), anti-NF- κ B (ab16502; 1:1,000), anti-TGF- β 1 (ab92486; 1:1,000), anti-TF (ab104513; 1:1,000), anti-PAI-1 (ab66705; 1:1,000), anti-PAR-1 (ab75607; 1:500) from Abcam (Cambridge, UK). All antibodies were diluted with 20% skimmed milk powder.

Statistical analysis. Statistical analysis was performed using SPSS 17.0 software (SPSS, Inc., Chicago, IL, USA), and the corresponding results are presented as the mean \pm standard deviation. Differences within groups were compared using Student's t-test, and among groups with one-way analysis of variance. $P < 0.05$ was considered to indicate a statistically significant difference.

Results

Effect of treatment on cell morphology of VECs. VECs from the normal control group demonstrated a round, spindle or polygonal shape with abundant and regularly arranged microvilli on the cell surface, an intact cell membrane, small intercellular space and visible cell connections. Compared with the normal group, VECs from the TNF- α group presented an increased cell volume and a less-regular shape, with irregularly distributed, stiff and broken microvilli. In addition, the number of cells within a single field at the same magnification was markedly greater. Compared with the TNF- α group, VECs from all treated groups displayed a marked improvement in cell morphology, cell size and the number and distribution of microvilli, and the number of cells in the field of view decreased (Fig. 1).

Effect of treatment on mRNA expression of NF- κ B, TGF- β 1, TF, PAR-1, PKC- α and PAI-1 in VECs. Compared with the normal group, mRNA expression of NF- κ B, TGF- β 1, TF, PAR-1 and PKC- α genes were significantly upregulated ($P < 0.05$) in the TNF- α -induced inflammatory VECs, indicating that expression of NF- κ B, TGF- β 1, TF, PAR-1 and PKC- α was increased following TNF- α stimulation. Interventions using either RTA or sinapine thiocyanate alone, or a combined treatment significantly inhibited mRNA expression of TGF- β 1 and NF- κ B (both $P < 0.05$) and markedly downregulated mRNA expression of TF, PAR-1 and PKC- α in TNF- α -induced inflammatory VECs; however, no significant differences were observed between these groups.

Meanwhile, PAI-1 mRNA expression was also found to be upregulated in the TNF- α -induced inflammatory VEC model ($P < 0.05$) and was positively correlated with the activity of TGF- β 1. PAI-1 mRNA expression was significantly downregulated in VECs treated either with RTA alone or RTA and sinapine thiocyanate (both $P < 0.05$) and markedly downregulated in VECs treated with sinopine thiocyanate alone compared with the TNF- α group (Table I and Fig. 2).

Effect of treatment on protein expression of NF- κ B, TGF- β 1, TF, PAR-1, PKC- α , and PAI-1 in VECs from each group. Compared with the TNF- α group, protein expression of TGF- β 1, TF, PAR-1, PAI-1 and PKC- α were all significantly decreased in the normal control and DMSO groups ($P < 0.05$). However, protein expression of NF- κ B, TGF- β 1, TF, PAR-1, PAI-1 and PKC- α were all significantly decreased in VECs treated with RTA, sinapine thiocyanate, and RTA and sinapine thiocyanate as compared with that in TNF- α -treated VECs (all $P < 0.05$); however no significant differences were observed between these groups (Table II and Figs. 3 and 4).

In addition, compared with the normal control group, PAI-1 protein expression was significantly upregulated in the TNF- α group ($P < 0.05$), indicating that PAI-1 expression was increased in TNF- α -stimulated VECs. Furthermore, PAI-1 expression was inhibited to varying degrees by treatment with RTA, sinapine thiocyanate, and RTA and sinapine thiocyanate and was significantly decreased in all three groups compared with the TNF- α group ($P < 0.05$; Table II, Figs. 3 and 4).

Discussion

TNF- α is a multifunctional, proinflammatory factor, secreted by activated macrophages that can directly damage VECs. After binding to the TNF- α receptor on the cell membrane of VECs, TNF- α exerts its biological effect via multiple pathways (11-15) to induce inflammation and alter coagulant/fibrinolytic function of VECs (16), leading to inflammation and coagulation. In the present study, a TNF- α -induced VEC injury model was established to investigate alterations in cell morphology and subcellular structures. The results demonstrated that TNF- α (5 μ g/l) successfully induced *in vitro* vascular endothelial injury, manifested by enlarged, irregularly-shaped cells with stiff and broken microvilli, irregularly distributed on the cell surface and a markedly increased number of cells in a single field of view under SEM. Conversely, following treatment with RTA, sinapine thiocyanate or RTA and sinapine thiocyanate, the cell morphology improved to a varying extent and the number of cells in a single field of view increased. This result

suggests that RTA and sinapine thiocyanate are able to antagonize TNF- α -induced VEC damage, manifested by a marked improvement in cell size and morphology of VECs as well as the quantity and distribution of microvilli.

The procoagulant effect during inflammation is achieved via multiple pathways, initiated by TF expression. Under normal physiological conditions, VECs exhibit antithrombotic and anticoagulant function, illustrated by extremely low or almost nil expression of TF (17). TF is activated via multiple pathways. Firstly, high TF expression may be induced during TNF- α -induced VEC injury or dysfunction (17), initiating the extrinsic coagulation pathway, leading to hemostatic imbalance and a shift towards coagulation/thrombosis. Secondly, the activation and nuclear translocation of NF- κ B is important in TF expression. Activated by TNF- α , NF- κ B dimers translocate into the nucleus, bind to specific sites on the DNA, and induce and accelerate the transcription of corresponding genes, leading to TF protein expression (18,19). Thirdly, TGF- β 1 released from activated platelets induces increased

TF expression in human umbilical vein endothelial cells (20). TGF- β 1 is a major factor regulating TF expression in VECs via the NF- κ B/TGF- β 1/SMADs signaling pathway (21). TGF- β 1 released from activated platelets is able to enhance the procoagulant activity in vascular endothelium by promoting TF generation by VECs. The underlying mechanisms may include increased TF expression via increased TGF- β 1 production and

MAPK activation (22,23). The present study demonstrates that TNF- α stimulation may result in enhanced expression of TGF- β 1, NF- κ B and TF in VECs and initiate the extrinsic coagulation pathway. In addition, the combined use of RTA and sinapine thiocyanate may inhibit the protein and mRNA expression of TF, TGF- β 1 and NF- κ B in a TNF- α -induced inflammatory VEC model, indicating that treatment with RTA

and sinapine thiocyanate directly reduces TF expression and indirectly inhibits TF expression by reducing TGF- β 1 and NF- κ B expression.

Following the initiation of the extrinsic coagulation pathway, TF enhances thrombin expression and binds to PAR on the cell surface. This activates the receptor-G protein-PLC-DG-PKC signaling pathway, which leads to increased expression and the development of coagulation during inflammation. Mediated

by signal transduction via Gq proteins, PAR-1 activates phospholipase C, which decomposes phospholipids and generates IP3. In turn, this triggers Ca^{2+} release from the endoplasmic reticulum, resulting in an increased concentration of cytosolic Ca^{2+} and further activation of PKC (24,25). PKC is one of the most important molecules involved in post-membrane signaling transduction and participates in a crucial cell-signaling transduction pathway for atherosclerosis (26).

The results from the present study demonstrate that mRNA and protein expression of PAR-1 and PKC- α is positively correlated with that of TF, TGF- β 1 and NF- κ B, indicating that the receptor-G protein-PLC-DG-PKC signaling pathway is activated following the initiation of the extrinsic coagulation pathway. In the present study, treatment with RTA and sinapine thiocyanate downregulated the protein and mRNA expression of PAR-1 and PKC- α , which suggests that the combined use of RTA and sinapine thiocyanate may further suppress the activation of the receptor-G protein-PLC-DG-PKC signaling pathway, thereby reducing the expression of blood coagulation factors during inflammation and inhibiting the procoagulant state of the vascular endothelium.

Furthermore, TGF- β 1 upregulates PAI-1 expression at the transcriptional level via the TGF- β 1/SMADs and TGF- β 1/MAPK signaling pathways (27,28). PAI is a serine protease inhibitor. Activated PAI, at physiological concentrations, inactivates tissue-type plasminogen activator (t-PA) by forming a 1:1 complex with t-PA, thereby balancing fibrinolytic activity (29). Decline in fibrinolytic activity is likely to be a critical risk factor for a variety of cardiovascular and cerebrovascular events. In addition, t-PA in the arterial wall activates plasminogen to plasmin, which in turn leads to the degradation of the extracellular matrix and fibrin deposited in the arterial intima (30). Under normal circumstances, there is a dynamic balance between plasmin and thrombin. However, when the vascular endothelium is injured, PAI-1 expression increases and leads to t-PA inactivation by binding to t-PA, leading to a decrease in plasmin concentration and a relative increase of thrombin expression (29). In addition, increased deposition of extracellular matrix and fibrin in the arterial wall might be a potential cause for vascular endothelial injury because this further promotes VEC injury and proliferation of smooth muscle cells.

The results of the present study demonstrated that PAI-1 activity is positively correlated with that of TGF- β 1. Compared with the model group, mRNA and protein expression of TGF- β 1 and PAI-1 in all the treatment groups was downregulated to varying extents. This result confirmed that the combined treatment with RTA and sinapine thiocyanate inhibits the TGF- β 1 signaling pathway and thereby downregulates PAI-1 expression, which may help with restoring the dynamic balance between plasmin and thrombin and reduce fibrin deposition on endothelial cells, thereby inhibiting the procoagulant state in the vascular endothelium.

In addition to phenotypical alterations in the vascular endothelium causing a shift from the anti-inflammatory and anti-coagulant to pro-inflammatory and pro-coagulant state, the role of the vascular endothelium in the maintenance of vascular homeostasis is gradually inhibited, which becomes an initiating factor and mediator for the endothelium-hypertension-cardiovascular events cascade. Therefore, reversing the prothrombotic state of the vascular endothelium is particularly important. The present study demonstrates that combined treatment with RTA and sinapine thiocyanate is able to downregulate the expression of coagulation-related factors during VEC injury, thus inhibiting the shift from anticoagulant and antithrombotic state to procoagulant and PTS. In addition, the underlying mechanism is partially associated with TF-mediated activation of the thrombin-receptor

signaling pathway that suppresses coagulation during inflammation and balances fibrinolysis to inhibit fibrin generation and deposition.
