Abstract. Abnormal expression of hypoxia inducible factor-1 α (HIF-1 α) is closely associated with various diseases. By detecting the mRNA and protein expression levels of microRNA 18b (miR-18b) and HIF-1a in placental tissues of preeclampsia (PE) patients and studying the effects of miR-18b on total cellular metabolic activity, migration and invasion in normal human trophoblast cell lines (HTR-8/SVneo), the present study aimed to investigate the effect of miR-18b on targeted regulation of HIF-1 α and its clinical significance in the development of PE. Expression levels of miR-18b and HIF-1a mRNA in PE placental tissues were detected by reverse transcription-quantitative polymerase chain reaction and corresponding expression levels of HIF-1a protein were analyzed by western blotting. miR-18b overexpression and inhibited miR-18b expression in HTR-8/SVneo cells, which were constructed by transfecting miR-18b mimic and inhibitor, respectively, were investigated and the total cellular metabolic activity, migration and invasion abilities in different groups of cells were compared. Expression levels of miR-18b were significantly reduced in PE placental tissues and miR-18b inhibitor-transfected HTR-8/SVneo cells, whereas the expression levels of HIF-1 α were significantly increased in PE placental tissues and significantly decreased in miR-18b mimic-transfected HTR-8/SVneo cells. Overexpression of miR-18b inhibited the expression of HIF-1 α and reduced the cell invasion, migration and viability of HTR-8/SVneo cells. However, inhibition of miR-18b expression promoted the expression of HIF-1a and increased the cell invasion, migration and total cellular metabolic activity of HTR-8/SVneo cells. The present study indicated that abnormal expression of HIF-1a exhibited in PE placental tissues was regulated by miR-18b. Furthermore miR-18b expression was demonstrated to affect cell invasion, migration and viability through target regulation of HIF-1 α . The results of the present study suggest that miR-18b and HIF-1 α may have important roles in the development of PE.

Introduction

Preeclampsia (PE), which is predominantly characterized by hypertension and proteinuria and is a pregnancy-specific disease that originates in the placenta, is a serious threat to maternal and perinatal life (1). Although PE is considered a common obstetric complication, the mechanism of pathogenesis remains to be fully elucidated. At present, the majority of studies suggest that abnormal differentiation and apoptosis in trophoblast cells results in cell dysfunction, changes in infiltration and spiral artery remodeling in trophoblast cells, which eventually leads to the occurrence of PE (2,3). Thus, the dysfunction of trophoblast cells is considered an important cause of PE. MicroRNA (miRNA) are a class of endogenous and highly conserved non-coding small RNA, with the length from 18 to 24 nucleotides. The basic function of miRNA is to bind to the specific pairing bases of target mRNA [i.e., miRNA-specific binding to the 3' untranslated region (3'UTR) of target mRNA], causing degradation or translational repression of the target mRNA and promoting post-transcriptional gene silencing (4). Previous studies suggest that miRNA have important roles in various basic physiological processes, such as cell growth, differentiation, proliferation and apoptosis (5-7). Furthermore, previous studies have indicated a series of expression imbalances between miRNA and target genes in PE placental tissues, which have resulted in cell dysfunction in placental tissues; thus, abnormal expression levels of miRNA have been demonstrated to be closely related to the occurrence of PE in PE patients (8-10). miR18b (miR-18b) is involved in the regulation of multiple diseases. It has been reported that miR-18b has a role as a tumor suppressor gene by targeting the MDM2-p53 pathway in melanoma (11). Moreover, miR-18b is abnormally expressed in gastric cancer (12), breast cancer (13) and nasopharynx cancer (14). The present study indicated that miR-18b exhibited pathologically low expression levels in PE placentas; however, the pathological mechanism of miR-18b in the pathogenesis of PE remains poorly studied (15).

Hypoxia inducible factor-1 (HIF-1) is a key transcriptional regulatory factor that mediates cellular adaptation to hypoxia microenvironment (16). HIF-1 is overexpressed in various cancers and precancerous lesions and is considered to be the

Key words: preeclampsia, microRNA 18b, hypoxia inducible factor-1 α

central initiating molecule of tumor angiogenesis (17). HIF-1 is a heterodimer that contains two subunits of HIF-1 α and HIF-1 β (18). Taylor (19) revealed that, under normoxic conditions, prolyl hydroxyl-lase domain proteins (PHD) were able to hydroxylate the proline residues in the oxygen-dependent degradation domain of the Q subunit and subsequently enhance the affinity of HIF-1 $\!\alpha$ and tumor suppressor protein (von Hippel-Lindau protein), ultimately promoting the combination of HIF-1 α to a ubiquitin-dependent proteolytic enzyme complex to enzyme hydrolysis. In the case of hypoxia, PHD activity decreased and HIF-1a rapidly gathered in the intracellular space, combined with β isoforms and was transferred to the nucleus to promote the transcription of hypoxia-responsive genes. Ietta et al (20) reported that HIF-1 was the key molecular component that mediated the regulation of hypoxia during trophoblast cell-associated invasion and differentiation processes. A previous study indicated that the expression levels of HIF-1 α are sustained throughout pregnancy (21). HIF-1 α expression in villus tissues is significantly increased in weeks 8 to 10 of pregnancy, the time point at which the placental oxygen content is lower (22). Additionally, HIF-1 α expression has been revealed to exhibit a clear downward trend in weeks 10 to 12 of pregnancy, the time point at which the placental oxygen content increases and the invasion ability of trophoblast cells subsequently peaks as maternal-fetal circulation has been established (22). These changes have notable influences on the functions of trophoblast cells and the entire placenta, indicating that HIF-1 α may have a close relationship with the pathogenesis of PE.

In the present study, the expression levels of HIF-1 α and miR-18b in placental tissues were detected and the roles of HIF-1 α and miR-18b in PE were analyzed. The present findings may further elucidate the pathogenesis mechanism of PE and provide a novel theoretical basis for the treatment of PE.

Materials and methods

Tissue specimen collection. A total of 50 pregnant women consisting of 25 PE patients and 25 normal controls were selected in the Obstetrics and Gynecology of Qingdao Municipal Hospital (Qingdao, China), between May 2014 and December 2014. The criteria used for diagnosis of pre-eclampsia were as follows: i) Systolic blood pressure of ≥140 mm Hg or diastolic blood pressure of ≥90 mm Hg occurring 20 weeks post-gestation in a woman whose blood pressure was previously normal; and ii) proteinuria, with excretion of ≥ 0.3 g in a 24-h period. All studied pregnant women had given birth via cesarean section and no significant difference (P>0.05) in age (20-35 years old) and gestational age (35-40 weeks) was exhibited between the patients of the PE group and the control group. All specimen collections were approved by the Ethics Committee of Qingdao Municipal Hospital and all subjects gave their informed written consent. All cases were confirmed by pathology, following surgery. Placental tissue samples were collected during cesarean section and immediately stored at -80°C for detection by reverse transcription-quantitative polymerase chain reaction (RT-qPCR) and western blotting. The present study was approved by the Ethics Review Board of Qingdao Municipal Hospital.

Reagents. Normal human trophoblast cell line (HTR-8/SVneo) cells were purchased from American Type Culture Collection (Manassas, VA, USA). TRIzol and Lipofectamine 2000 were purchased from Invitrogen (Thermo Fisher Scientific, Inc., Waltham, MA, USA). miR-18b mimics/inhibitors were purchased from Shanghai GenePharma Co., Ltd. (Shanghai, China). Rabbit anti-human HIF-1α polyclonal antibody was purchased from Abcam (ab82832; Cambridge, MA, USA). The reverse transcription kit, SYBR PrimeScript miRNA RT-PCR kit and SYBR-Green real-time PCR reagents were all purchased from Takara Biotechnology Co., Ltd. (Dalian, China).

Cell culture and transfection. HTR-8/SVneo cells were cultured in Dulbecco's modified Eagle's medium (DMEM)-F12 complete culture medium (Hyclone, Logan, UT, USA) supplemented with 20% fetal bovine serum (FBS; Sijiqing, Hangzhou, China) at 4x10⁵ per well and maintained at 37°C in a humidified atmosphere of 5% CO₂ and 20% O₂. For transfection, HTR-8/SVneo cells were seeded in 6-well plates and cell transfection was performed when ~70% confluency was achieved. Four groups were allocated, consisting of the hsa-miR-18b mimic transfected group (transfected with mimic), hsa-miR-18b inhibitor transfected group (transfected with inhibitor), negative control transfected group (transfected with negative controls) and non-transfected control group (blank/no transfection preformed). Lipofectamine 2000 transfection reagents were used for transfection. Cells were harvested at 48 h following transfection.

RNA extraction and reverse transcription. Total RNA were extracted from placental tissues and HTR-8/SVneo cells using the TRIzol and phenol chloroform method. RNA was reverse transcribed into cDNA, and the cDNA was stored at -20°C. For miRNA reverse transcription, the reverse transcription system consisted of 6 μ l RNA, 10 μ l miRNA reaction buffer mix (2X), 2 μ l BSA (0.1%) and 2 μ l miRNA PrimeScript RT Enzyme mix. Reverse transcription was performed at 37°C for 60 min.

RT-qPCR analysis. mRNA expression levels of miR-18b and HIF-1a in tissues and HTR-8/SVneo cells were detected by SYBR-Green quantitative PCR. U6 and GAPDH were used as internal controls of miR-18b and HIF-1a, respectively. RT-qPCR for miR-18b was performed in 25 μ l of reaction system containing 12.5 µl SYBR Premix Ex Taq, 0.5 µl forward primer (5'-UAAGGUGCAUCUAGUGCAGUUAG-3'), 1 µl Uni-miR qPCR primer (5'-CCAUAAGGUGCAUCUAGUGCAGU-3'), 2 μ l template and 8.5 μ l double-distilled H₂O. RT-qPCR for miR-18b was performed using a verititm 96-well thermal cycler (Applied Biosystems; Thermo Fisher Scientific, Inc.) using the following procedure: 95°C for 30 sec, followed by 40 cycles of 94°C for 5 sec and 60°C for 20 sec. RT-qPCR for HIF-1 α was performed in a 20- μ l reaction mixture containing 10 µl SYBR Premix Ex Taq, 0.5 µl forward primer (5'-TCAAAGTCGGACAGCCTCAC-3'), 0.5 µl reverse primer (5'-TAGCTGCATGATCGTCTGGC-3'), 1 µl cDNA template and 8 μ l double-distilled H₂O. RT-qPCR for HIF-1 α was performed using the following procedure: 95°C for 10 min, followed by 40 cycles of 94°C for 1 min, 60°C for 40 sec and 72°C for 40 sec. Each experiment was performed in triplicate.

The relative expression of HIF-1 α was calculated using the $2^{-\Delta\Delta Cq}$ method (23).

Western blotting. Total proteins (50 μ g) were extracted from placental tissues and HTR-8/SVneo cells by incubating with pre-cold RIPA lysate (50 mM Tris-base, 1 mM EDTA, 150 mM NaCl, 0.1% SDS, 1% Triton X-100 and 1% sodium deoxycholate). The concentration of protein was determined using a BCA Protein Assay kit (Beyotime Institute of Biotechnology, Shanghai, China). Proteins of 10 μ l were subjected to a 12% SDS-PAGE electrophoresis (100 V) and transferred to a PVDF membrane (Merck Millipore, Darmstadt, Germany). The membrane was blocked with 5% skimmed milk in Tris-buffered saline with 0.1% Tween-20 for 1 h at room temperature. The primary antibodies anti-HIF-1α (ab113642; 1:1,000; Abcam) and anti-GAPDH (ab8245; 1:2,000; Abcam) for detecting the expression of endogenous GAPDH as an internal reference were incubated at 4°C overnight. After washing with PBS with Tween-20 for 15 min three times, the secondary antibodies horseradish peroxidase-conjugated goat anti-rabbit antibodies (ab6789, 1:1,000, Abcam) were added and incubated for 1 h at room temperature and then washed by PBS with Tween-20 for 15 min three times. Chemiluminescence reagent (EMD Millipore, Billerica, MA, USA) was used for color development. The protein was placed in the ECL luminescent solution and the image signal was obtained and analyzed by the image lab software (Bio-Rad Laboratories, Inc., Hercules, CA, USA). The gray value of the target protein band was compared with that of the GAPDH. The ratio of the gray value of the band is the relative content of the target protein.

Cell migration. Effects of miR-18b on the migration of HTR-8/SVneo cells were measured using a Transwell chambers assay (Corning Inc., Corning, NY, USA). Transfected cells were trypsinized, resuspended to $5x10^5$ cells/ml in DMEM supplemented with 0.1% bovine serum albumin (BSA). Cells (200 μ l with the density of $5x10^5$ cells/ml) were added to the upper compartment of the chamber. To the lower compartment, DMEM supplemented with 20% FBS was added as the chemotactic factor. Once incubated at 37°C for 4 h, cells inside the upper compartment of the chamber were wiped and the cells migrated through to the lower compartment of the chamber were fixed with 100% methanol. Evaluation of migrated cells was performed under a light microscope at a magnification of x400 following 0.1% crystal violet cell staining.

MTT assay. The effect of miR-18b on total cellular metabolic activity of HTR-8/SVneo cells was studied using an MTT Cell Viability Assay kit (Beyotime Institute of Biotechnology). HTR-8/SVneo cells were cultured in DMEM supplemented with 10% BSA at 37°C in a humidified atmosphere containing 5% CO₂. Subsequently, cells were transfected with hsa-miR-18b mimic, hsa-miR-18b inhibitors, negative control vector or not transfected (blank used for comparison) in 96-well plates at a density of 3,000 cells/well using Lipofectamine 2000, according to the manufacturer's instructions. For the MTT assay, each sample was provided with three parallel wells and 15 μ l of MTT was added to each well at 24, 48 and 72 h following transfection. Following 4-h incubation at 37°C, the supernatant was removed, dimethyl sulfoxide (10 μ l/well) was

added and incubated at 37°C for 4 h to dissolve the purple formazan and the absorbance value of each well was read at a wavelength of 492 nm.

Cell invasion assay. The invasive ability of HTR-8/SVneo cells (ATCC) seeded in 24-well plates was examined using growth factor-depleted matrigel invasion chambers (BD Biosciences, San Jose, CA, USA) and Transwell inserts (Corning, Inc., NY, USA). A total of 500 µl serum-free DMEM (HyClone) was added to Matrigel chambers, incubated at room temperature for 1 h to hydrate matrix glue and the remaining medium was removed. Subsequently, 750 µl DMEM supplemented with 20% FBS (Sijiqing, Hangzhou, China) was added to the lower chamber. Cells were transfected with hsa-miR-18b mimic, hsa-miR-18b inhibitors, negative control vector or not transfected (blank). Transfected cells were trypsinized, centrifugally collected and resuspended to 4x10⁵ cells/ml in DMEM supplemented with 0.1% BSA. Cells (500 μ l with the density of 4x10⁵ cells/ml) were added to the upper compartment of the chamber. Following incubation at 37°C in a humidified atmosphere containing 5% CO₂ for 18 h, the cells inside the upper compartment of the chamber were wiped using a cotton swab and the cells invaded through to the lower compartment of the chamber with 100% methanol were fixed. Evaluation of migrated cells was performed under a light microscope following 0.1% crystal violet (Beyotime Institute of Biotechnology) cell staining.

Statistical analysis. All statistical analyses were performed using Statistical Package for Social Sciences software for Windows (version 16.0; SPSS, Inc., Chicago, IL, USA). Each experiment was repeated in triplicate (n=3). Data are presented as mean \pm standard deviation. All data were analyzed with a normality test. Variance analysis was applied for multiple sets of measurement data analysis and Student's t-test was applied for two sets of data analysis. P<0.05 was considered to indicate a statistically significant difference.

Results

Expression levels of miR-18b and HIF-1 α in PE and normal placental tissues detected by RT-qPCR. mRNA expression levels of miR-18b and HIF-1 α in PE and normal placental tissues were detected by RT-qPCR. As indicated in Fig. 1, the mRNA expression levels of HIF-1 α mRNA in PE placental tissues were significantly increased when compared with normal placental tissues (P<0.05; Fig. 1A) and the mRNA expression levels of miR-18b in PE placental tissues were significantly decreased when compared with normal placental tissues (P<0.05; Fig. 1B). These results indicate that the down-regulated mRNA expression levels of miR-18b may be related to the presence of HIF-1 α in placental tissues.

Prediction of hsa-miR-18b target genes. Target genes of hsa-miR-18b were predicted using TargetScan software (http://www.targetscan.org/) as described previously (24). Results indicated a targeted regulatory relationship between HIF-1 α and miR-18b and the specific regulatory binding sequences were shown in Fig. 2. The present finding suggests that HIF-1 α is one of the target genes of miR-18b.

Figure 2. Predicted specific regulatory binding sequences of miR-18b to HIF-1 α using Targetscan software. HIF-1 α , hypoxia inducible factor-1 α ; miR-18b, microRNA 18b.

Protein expression of HIF-1 α in placental tissues. Protein expression levels of HIF-1 α in PE and normal placental tissues were detected by western blotting. Consistent with the trend observed for HIF-1 α mRNA expression, the protein expression levels of HIF-1 α in PE placental tissues were significantly increased when compared with normal placental tissues (P<0.05; Fig. 3). This result indicates that the abnormal expression of HIF-1 α is closely related to the occurrence of PE.

Expression of HIF-1a in transfected HTR-8/SVneo cells. To verify the regulation of miR-18b on the expression of HIF-1 α gene, mRNA expression levels of HIF-1α in hsa-miR-18b mimic-transfected, hsa-miR-18b inhibitor-transfected and negative control vector-transfected HTR-8/SVneo cells (NC) and normal HTR-8/SVneo cells (blank) were compared by RT-qPCR. mRNA expression levels of miR-18b were significantly increased in miR-18b mimic transfected HTR-8/SVneo cells, which were >1.7-fold higher when compared with the NC and blank groups (P<0.05; Fig. 4A). Furthermore, the mRNA expression levels of miR-18b were significantly decreased in miR-18b inhibitor-transfected HTR-8/SVneo cells, which were <30% of the mRNA expression levels exhibited by miR-18b in the NC and blank groups (P<0.05; Fig. 4A). Moreover, the mRNA and protein expression levels of HIF-1a gene were compared. When compared with the expression levels exhibited in the NC and blank groups, overexpression of miR-18b resulted in significantly decreased expression levels of HIF-1a in HTR-8/SVneo cells at protein (P<0.05; Fig. 4B and C) and mRNA level (P<0.05; Fig. 4D). Conversely, inhibited expression of miR-18b resulted in significantly increased expression levels of HIF-1 α in HTR-8/SVneo cells at protein (P<0.05; Fig. 4B and C) and mRNA level (P<0.05; Fig. 4D). These results suggest that overexpression of miR-18b may inhibit the transcription and translation of HIF-1 α gene.

miR-18b inhibits cell migration and invasion ability of HTR-8/SVneo cells. Possible effects of miR-18b on the cell migration and invasion ability of HTR-8/SVneo cells were studied using the cell migration and invasion assay. When compared with the NC and blank groups, overexpression of miR-18b resulted in significantly decreased cell migration and invasion abilities of HTR-8/SVneo cells (P<0.05; Fig. 5); however, inhibited expression of miR-18b resulted in significantly increased cell migration and invasion abilities of HTR-8/SVneo cells (P<0.05; Fig. 5). These results suggest that miR-18b may inhibit the cell migration and invasion abilities of HTR-8/SVneo cells.

miR-18b inhibits total cellular metabolic activity of *HTR-8/SVneo* cells. Possible effects of miR-18b on the total cellular metabolic activity of HTR-8/SVneo cells were studied using MTT assays. When compared with the NC and blank groups, overexpression of miR-18b resulted in significantly decreased total cellular metabolic activity of HTR-8/SVneo cells; however, inhibited expression of miR-18b resulted in significantly increased total cellular metabolic activity of HTR-8/SVneo cells (P<0.05; Fig. 6). These results indicate that miR-18b may inhibit the total cellular metabolic activity of HTR-8/SVneo cells.

Discussion

It has been reported that abnormalities of placental trophoblast cells may be associated with the pathogenesis of PE (25,26). Invasion disorder of trophoblast cells is a central link in the development of PE and placenta ischemia, and hypoxia of PE has been indicated to further aggravate the invasion disorder of trophoblast cells, subsequently forming a vicious cycle (27).

HIF-1 α is able to regulate the transcription of various hypoxia-sensitive factor genes (28). Studies have indicated that the 401 to 603 amino acid residues of HIF-1 α have an oxygen-dependent degradation domain (29,30). Under normoxic conditions, HIF-1 α is degraded and therefore it is difficult to detect the presence of HIF-1 α . However, in the case of hypoxia, the degradation of HIF-1 α is blocked and HIF-1 α accumulates in the nucleus (31). The accumulated HIF-1 α combines with HIF-1 β in the nucleus to form HIF,

which further activates the transcription and expression of hypoxia-sensitive factor genes by binding to the hypoxia response elements (32). HIF-1 is able to regulate the expression of various factors, such as the vascular endothelial growth factor (VEGF), VEGF receptors (33) and glucose transporters, which have important roles in erythropoiesis, cell proliferation and differentiation (34). In the present study, mRNA and protein expression levels of HIF-1 α in PE placental tissues were significantly higher than that in the normal population.

It remains unclear whether specific miRNA may participate in the pathogenesis of PE. Mature miRNA combine with other proteins to form miRNA-induced silencing complexes, recognize and bind to target genes by complete or incomplete complementary binding to the 3'-UTR of the target mRNA and regulate the expression of target genes (35). Pineles *et al* (36) reported that differential expression of miR-182 and miR-210 was exhibited in the placentas of PE patients and normal individuals. In addition, Zhu *et al* (37) indicated that the expression of 34 miRNA was disordered in PE placentas, including 23 miRNA upregulated and 11 downregulated. Further functional investigation in their study indicated that these miRNA have important roles in the process of placenta development

and PE occurrence and development (37). Wang *et al* revealed that miR-18b was highly expressed in non-metastatic colon cancer specimens by miRNA chip detection (38). Furthermore, a previous study demonstrated that the expression of miR-18b was elevated in human basal cell carcinoma, suggesting that miR-18b may be involved in the occurrence and development of basal cell carcinoma (39). It has been suggested that in different tissues, the function and expression of miR-18b may differ (40).

The villous trophoblast bilayer covering the placental villi consists of the underlying cytotrophoblast layer and outer syncytiotrophoblast layer. A population of cells, extravillous trophoblasts (EVTs), detach from placental villi in the first 20 weeks of pregnancy and invade the uterine wall, remodeling the maternal uterine arteries in normal pregnancy (41). HTR-8/SVneo cells are non-cancerous cells isolated from EVT (42). In the present study, HTR-8/SVneo cells were used to investigate the function of miR-18b in placenta trophoblast cells. miR-18b mimic and miR-18b inhibitor were transfected into HTR-8/SVneo cells and the changes of related cellular functions were studied. RT-qPCR results showed that the mRNA expression levels of miR-18b were significantly increased in miR-18b mimic-transfected cells and significantly decreased in miR-18b inhibitor-transfected cells, suggesting that miR-18b mimic and inhibitor were able to regulate the expression of miR-18b. Using RT-qPCR and western blotting, the present study revealed that overexpression of miR-18b significantly inhibited the expression of HIF-1 α , whereas inhibition of miR-18b significantly increased the expression of HIF-1 α in HTR-8/SVneo cells. Subsequently, the effects of target regulation of miR-18b on HIF-1 α with respect to cell biological functions were further investigated and the mechanism of abnormal expression of miR-18b exhibited in the development of PE was explored. The present results indicated that, in miR-18b-overexpressing HTR-8/SVneo cells, the total cellular metabolic activity, migration and invasion ability were significantly decreased, whereas these abilities were significantly increased when the expression of miR-18b was inhibited. These results suggest that miR-18b may be involved in the development of PE through targeted regulation of HIF-1 α , subsequently affecting the cell migration, invasion and viability of HTR-8/SVneo cells.

The present study exhibited some limitations. One limitation was that the HTR8-SVneo cell line, a model of primary EVT used in the present study, is proliferative and may behave differently to primary cells. Furthermore, miR-18b expression in human placental tissue was obtained at the end of pregnancy and not at the first 20 weeks of pregnancy, during which uterine spiral artery remodeling occurs. Therefore, whether altered miR-18b expression was the cause or the consequence of pre-eclampsia is unknown. Moreover, we did not further investigate the clinical implication of *in vivo* reduced miR-18b expression or evaluate the clinical benefits. Further studies are required to overcome these limitations.

In conclusion, we believe that the present study indicated that miR-18b may act as an inhibitory factor in the pathogenesis of PE, and that miR-18b and HIF-1 α have a critical role in the development of PE. We suggest that designing targeted therapies towards miR-18b and HIF-1 α and clinically monitoring the expression of miR-18b and HIF-1 α in placental tissue of PE patients may be helpful in improving the diagnosis and prognosis of PE.
