**Abstract.** The mortality rate of ovarian cancer is the highest out of all gynecological malignancies worldwide. Therefore, it is important to understand the mechanisms of ovarian cancer, identify new biomarkers and develop targeted drugs. The role and molecular mechanisms of hsa-microRNA (miR)-411-5p in ovarian cancer have not been fully elucidated. The present study investigated the ovarian cancer cell lines OVCAR-8 and SKOV3. After transfection with miRNA mimics, cell proliferation was monitored by a proliferation assay. Furthermore, cell migration was measured by a cell wound healing assay and cell invasion was measured by Matrigel invasion assays. A miRNA luciferase reporter assay was used to analyze the relationship between miRNAs and the target gene HMMR, which was then further evaluated by gene differential analysis. In the current study, hsa-mir-411-5p was identified as a miRNA regulator of the hyaluronan mediated motility receptor, which negatively regulated the activity of ERK1/2 and ultimately inhibited ovarian cancer cell proliferation and motility. Although hsa-mir-411-5p may have different roles in other types of cancer, the present study suggested that miR-411-5p functions as a negative tumor regulator in ovarian cancer cells, displaying the potential of miR-411-5p as a biomarker for ovarian cancer.

## Introduction

Ovarian cancer is the third most common gynecological cancer worldwide, and has the highest mortality rate of all gynecological malignancies (1,2). The 5-year survival rate for patients with early ovarian cancer (stage I or II) is 80-90%, compared

with the survival rate of patients with stage III and IV disease, which is only 25% (3,4). Only 30% of American patients with ovarian cancer are diagnosed in the early stages in 2016 (3,4). In patients with recurrent ovarian cancer, treatment is less effective than in patients with a first time diagnosis of ovarian cancer (5). As the number of relapses increases for a particular individual, the disease remission period is reduced (5). At present, there is no effective preventive strategy for ovarian cancer (5). Interventions that reduce the risk of ovarian cancer are particularly important given the limited screening options and high mortality rates, which have not significantly changed over the past several decades (5). Therefore, ovarian cancer is currently a major public health concern. The molecular mechanisms underlying the proliferation, migration and invasion of ovarian cancer cells require further investigation to identify new biomarkers and develop targeted drugs.

MicroRNAs (miRNAs/miRs) are non-coding RNAs ~22 nucleotides in length, which are involved in cell homeostasis and tumorigenesis (6). The abnormal expression of miRNAs in ovarian cancer is closely associated with the progression and clinical prognosis of the disease (7,8). A number of carcinogenic pathways may influence the same miRNA, and equally, a number of miRNAs may control a post-transcriptional program that affects numerous target genes (6,7). miRNAs are often downstream effectors of tumor relevant protein kinases or mutations, and therefore, targeting miRNAs may be a strategy to increase drug specificity and overcome drug resistance (6,8).

The function and expression of miR-411 has been studied in several types of cancer (9-12). A number of previous studies have reported that miR-411 may function as an oncogene in osteosarcoma and lung and hepatocellular carcinoma (9-12). Contrastingly, a number of studies have reported that miR-411 functions as a tumor suppressor in oral, cervical, breast and colorectal cancer, as well as renal cell carcinoma and glioma (13-21). At present, the role of hsa-mir-411-5p (also known as miR-411-5p) in the development of ovarian cancer is not completely understood. However, it has been reported that the expression of hsa-mir-411-3p in the stable state is low, which is unstable and easy to degrade (22). The present study explored the mechanisms of hsa-mir-411-5p in ovarian cancer cells *in vitro*.

**Key words:** ovarian cancer, hsa-microRNA-411-5p, proliferation, invasion, hyaluronan mediated motility receptor

## Materials and methods

**Cell culture and transfection.** The ovarian cancer cell lines OVCAR-8 and SKOV3 were purchased from The Cell Bank of Type Culture Collection of the Chinese Academy of Sciences and American Type Culture Collection, respectively. Cells were maintained in RPMI-1640 medium (Gibco; Thermo Fisher Scientific, Inc.) supplemented with 10% FBS (Gibco; Thermo Fisher Scientific, Inc.), at 5% CO<sub>2</sub> and 37°C. 293 cells (The Cell Bank of Type Culture Collection of the Chinese Academy of Sciences) were cultured in DMEM (Gibco; Thermo Fisher Scientific, Inc.) supplemented with 4,500 mg/l glucose and 10% FBS. The OVCAR-8 and SKOV3 cells were transfected with 25 nM negative control mimic (MISSION® miRNA, Negative Control 1; cat. no. HMC002; Sigma Aldrich; Merck KGaA) or miR-411-5p mimic (MISSION microRNA Mimic hsa-miR-411-5p; cat. no. HMI0558; Sigma-Aldrich; Merck KGaA) at 24 h after seeding, and cells were seeded into 6-well plates at a density of 1x10<sup>6</sup> cells/well. The sequences used were as follows: Negative control mimic forward, 5'-[AmC6]UGA ACAGUGUUACGUACGAUACC[dT][dT]-3', and reverse 5'-GGUUCGUACGUACACUGUUCA-3'. hsa-miR-411-5p mimic forward 5'-CGUACGCUAUACGGUCUAUCU A[dT][dT]-3', and reverse 5'-UAGUAGACCGUAUAGCGU ACG-3'. Transfection was carried out using Lipofectamine® RNAiMAX Transfection reagent (Thermo Fisher Scientific, Inc.) according to the manufacturer's instructions.

**IncuCyte proliferation assay.** OVCAR-8 and SKOV3 cells 2,000 cells/well were seeded into 96-well plates and allowed to adhere at 37°C and 5% CO<sub>2</sub>. After transfection for 12 h with miRNA mimics, cell proliferation was monitored by analyzing the occupied area (% confluence) of cell images at 0, 24, 48 and 72 h time points using the IncuCyte Live Cell Analysis system (Essen BioScience) according to the manufacturer's instructions.

**Cell wound healing assay.** OVCAR-8 and SKOV3 cells (1.5x10<sup>4</sup>/well) were seeded into 96-well ImageLock plates for 24 h in RPMI-1640 medium supplemented with 10% FBS at 37°C and 5% CO<sub>2</sub>. Following serum starvation (RPMI-1640 medium only) for 12 h at 37°C and 5% CO<sub>2</sub>, scratch wounds were made by the IncuCyte™ Cell Migration kit (Essen BioScience), using the 96-pin wound making tool (WoundMaker). Subsequently, cells were cultured in RPMI-1640 medium supplemented with 4% FBS for 24 h at 37°C and 5% CO<sub>2</sub>. Images were automatically monitored and analyzed every 4 h for 24 h by the IncuCyte Live Cell Analysis system (Essen BioScience; magnification, x10). Data were processed and analyzed using IncuCyte™ Cell Migration Software Application Module (Essen BioScience) for 24 h. Data are presented as the wound width.

**Cell invasion assay.** OVCAR-8 and SKOV3 cells (~5x10<sup>4</sup>-1x10<sup>5</sup>) were resuspended in serum-free RPMI-1640 medium and seeded in the top portion of a BioCoat Matrigel Invasion Chamber (Corning, Inc.). The lower compartment of the chamber contained RPMI-1640 medium supplemented with 10% FBS as a chemoattractant. After a 28-h incubation at 37°C and 5% CO<sub>2</sub>, cells on the upper side of the membrane were

removed, washed with PBS and fixed in 50% ethanol for 15 min at room temperature. Subsequently, cells were stained with Coomassie brilliant blue for 15 min at room temperature and counted under 10 different microscopic fields using an inverted light microscope (Leica Microsystems; magnification, x100).

**RNA isolation and reverse transcription-quantitative PCR (RT-qPCR).** To measure miRNA expression, total RNA was isolated from cultured OVCAR-8 and SKOV3 cells using the mirVana™ miRNA Isolation kit with phenol (Ambion; Thermo Fisher Scientific, Inc.). The mature form of miRNAs were detected using the TaqMan® Advanced miRNA cDNA Synthesis kit with TaqMan Fast Advanced Master mix (Thermo Fisher Scientific, Inc.). The hsa-miR-411-5p TaqMan Advanced miRNA assay kit (assay ID, 478086\_mir) and the hsa-miR-26a-5p TaqMan Advanced miRNA assay kit (assay ID, 477995\_mir), which was an internal control, were purchased from Thermo Fisher Scientific, Inc. RT-q PCR was performed by Applied Biosystems 7900HT Fast Real-time PCR system (Applied Biosystems; Thermo Fisher Scientific, Inc.). The relative expression was calculated by 2<sup>-ΔΔC<sub>q</sub></sup> method (23) and expression levels were normalized to hsa-miR-26a-5p.

To investigate the effects of miRNA-411-5p over-expression on the potential miRNA target gene HMMR, total RNA from OVCAR-8 and SKOV3 cells was isolated using the RNeasy Plus Mini kit (Qiagen Sciences, Inc.; cat. no. MD 20874) according to the manufacturer's protocol. RNA was reverse transcribed into cDNA using the High-Capacity cDNA Reverse Transcription kit (Thermo Fisher Scientific, Inc.) according to the manufacturer's protocol. PCR was performed in triplicate using SYBR® Select Master mix (Thermo Fisher Scientific, Inc.) on a 7900HT Fast Real-time PCR system (Applied Biosystems; Thermo Fisher Scientific, Inc.). The primer sequences used were as follows: HMMR forward, 5'-CCAGGTGCTTATGATGTTAAACT-3' and reverse, 5'-TGAGATTCTTCTTTGATTCCTCA-3'; and β-actin forward, 5'-ATTGGCAATGAGCGGTTCCG-3' and reverse, 5'-CGTGGATGCCACAGGACTCC-3'. The following thermocycling conditions were used: 95°C for 5 min; 40 cycles of 95°C for 10 sec, 60°C for 20 sec and 72°C for 20 sec. Relative expression was calculated using the 2<sup>-ΔΔC<sub>q</sub></sup> method (23) and expression levels were normalized to β-actin.

**Bioinformatics analysis and Luciferase reporter assay.** starBase (version 2.0; starbase.sysu.edu.cn) online database was used to predict that HMMR was a target of miRNA-411-5p. The human HMMR 3'UTR fragment (337 bp) was PCR-amplified from the genomic DNA and subcloned into the pMIR-REPORT luciferase construct (Thermo Fisher Scientific, Inc.) using the following cloning primers: Forward, 5'-TTGGTCCTACCTATTATCCTTCTA-3'; reverse, 5'-AATGACTTACTGTGTAATTTTATTTTC-3'. The mutant HMMR 3'UTR was made using a QuikChange Site-directed Mutagenesis kit (Agilent Technologies, Inc.) and confirmed using Sanger sequencing. 293 cells of 60% confluence in 24-well plates were co-transfected with the pMIR-REPORT firefly luciferase reporter gene construct, the pRL-TK Renilla luciferase construct (for normalization) and 25 nM miRNA mimics per well using Lipofectamine 2000 reagent (Invitrogen; Thermo Fisher Scientific, Inc.). Cell extracts were

prepared 48 h after transfection and the luciferase activity was measured using the Dual-Luciferase Reporter Assay system (Promega Corporation).

**Western blotting.** Total protein from OVCAR-8 and SKOV3 cells was extracted using RIPA buffer (Beyotime Institute of Biotechnology). Total protein was quantified using a bicinchoninic acid assay kit (Beyotime Institute of Biotechnology). 40  $\mu$ g protein/lane was separated on a 10% SDS-PAGE gel and then transferred to Hybond membranes (GE Healthcare). Membranes were blocked for 1 h in 5% milk in TBST at room temperature. For immunoblotting, membranes were incubated overnight at 4°C with antibodies targeted against HMMR (cat. no. ab124729; 1:1,000; Abcam), phosphorylated-Erk1/2 (cat. no. 4377; 1:1,000; Cell Signaling Technology Europe, B.V.), Erk1/2 (cat. no. 9102; 1:1,000; Cell Signaling Technology Europe, B.V.) and GAPDH (cat. no. sc-25778; 1:1,000; Santa Cruz Biotechnology, Inc.). Subsequently, membranes were incubated with anti-rabbit or anti-mouse horseradish peroxidase conjugated IgG (cat. no. 111-035-003 and 115-035-003; 1:20,000; Jackson ImmunoResearch Laboratories, Inc.) for 1 h at room temperature. Bands were visualized by ECL-Plus detection reagents (Santa Cruz Biotechnology, Inc.).

**Oncomine gene differential analysis by Oncomine.** Differentially expressed HMMR mRNA between 586 ovarian serous cystadenocarcinoma and 8 normal ovarian tissues was analyzed by Oncomine ([www.oncomine.org](http://www.oncomine.org)). Filters were set up as: Gene, HMMR, cancer type, ovarian cancer, dataset type, The Cancer Genome Atlas (TCGA) datasets. The data were grouped by cancer and normal type, and only samples included in the analysis are shown.

**Statistical analysis.** SPSS 20.2 software (IBM Corp.) was used to analyze the data. Data are presented as the mean  $\pm$  SEM. Differences between groups were assessed using a paired Student's t-test.  $P < 0.05$  was considered to indicate a statistically significant difference. StarBase (version 2.0; <http://starbase.sysu.edu.cn/>) online database provided the correlation analysis between miR-411-5p expression and HMMR mRNA level. The correlation between miR-411-5p and HMMR was further investigated using patient sample information from the starBase online database.

## Results

**miR-411-5p is a potent suppressor of ovarian cancer proliferation, migration and invasion.** The effects of miR-411-5p on the human ovarian cancer cell lines OVCAR-8 and SKOV3 were investigated using a miR-411-5p mimic. OVCAR-8 and SKOV3 cells were cultured and transfected with the negative control or the miR-411-5p mimic. At 48 h after transfection, the miR-411-5p expression level was significantly increased ( $P < 0.001$ ) in the miR-411-5p mimic groups, compared with the negative control groups, measured by RT-qPCR (Fig. 1). Furthermore, miR-411-5p significantly inhibited cell proliferation ( $P < 0.001$ ) in both the OVCAR-8 and the SKOV3 cell lines compared with the negative control, at all time points (Fig. 2A). Wound healing and Matrigel invasion assays were carried out to evaluate the effect of the

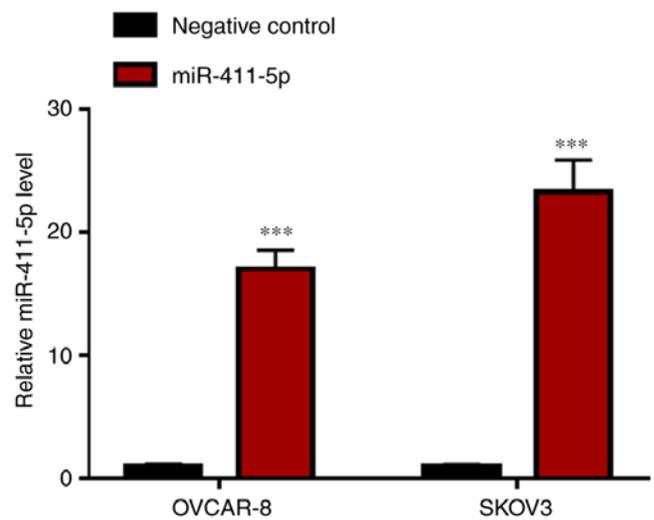

Figure 1. miR-411-5p mRNA levels in OVCAR-8 and SKOV3 cells following transfection with a negative control or miR-411-5p mimic, confirmed by reverse transcription-quantitative PCR. The Student's t-test was used to assess the difference. Error bars denote the SEM. \*\*\* $P < 0.001$  vs. the negative control. miR, microRNA.

overexpression of miR-411-5p on the migration and invasion of ovarian cancer cells, respectively. The results of the cell wound healing assay suggested that wound healing was decreased ( $P < 0.001$ ) at 8 h (OVCAR-8 and SKOV3), 12 h (OVCAR-8 and SKOV3) and 16 h (SKOV3) in the miR-411-5p group compared with the negative control group (Fig. 2B), which indicated that miR-411-5p suppressed ovarian cancer cell migration. The results of the Matrigel invasion assay displayed that cell invasion was significantly suppressed ( $P < 0.01$ ) in the miR-411-5p group compared with the negative control group (Fig. 2C).

**miR-411-5p directly targets HMMR.** To identify the potential target of miR-411-5p in ovarian cancer cell lines, starBase (version 2.0; [starbase.sysu.edu.cn](http://starbase.sysu.edu.cn)) online database was used to predict the candidate downstream target genes. The results suggested that the 3'-UTR of HMMR contained putative binding sites for miR-411-5p (Fig. 3A). To further confirm whether HMMR was the direct target of miR-411-5p, the 3'-UTR of HMMR was synthesized and cloned into a luciferase reporter plasmid to construct dual luciferase reporter gene plasmids including the pmir-HMMR 3'-UTR wild-type and pmir-HMMR 3'-UTR mutant. The dual luciferase reporter gene plasmids were co-transfected into 293 cells with the negative control or miR-411-5p mimic. The results indicated that 293 cells co-transfected with the pmir-HMMR 3'-UTR wild-type plasmid and the miR-411-5p mimic significantly decreased the relative luciferase activity compared with co-transfection with the negative control ( $P < 0.001$ ; Fig. 3B). However, co-transfection with the pmir vector or pmir-HMMR 3'-UTR mutant plasmid plus the miR-411-5p or negative control mimic did not significantly influence the relative luciferase activity of 293 cells (Fig. 3B). These results illustrated that HMMR was a direct downstream target of miR-411-5p. The correlation between miR-411-5p and HMMR was further investigated using patient sample information from the starBase online database. miR-411-5p expression from miRNA sequencing displayed a significant negative correlation

explored. The results suggested that ovarian cancer cells transfected with the miR-411-5p mimic displayed reduced HMMR mRNA and protein expression levels, as well as reduced ERK1/2 signaling pathway activity (Fig. 4A and B). Furthermore, differential HMMR mRNA expression between paired ovarian serous cystadenocarcinoma and normal tissue was analyzed by Oncomine. The results suggested that HMMR mRNA expression in ovarian serous cystadenocarcinoma was significantly higher (P<0.001) than that in normal ovarian tissue (Fig. 5).

**Discussion**

The biological role of miR-411 in ovarian cancer cells is not well understood (25), however, it has been reported that

miR-411 is downregulated in ovarian cancer cells (25). To the best of our knowledge, the present study is the first to demonstrate the regulatory molecular mechanism of miR-411-5p in the malignant biological behavior of ovarian cancer cells.

A number of previous studies have reported that miR-411 plays an important role as an oncogene in tumorigenesis by negatively regulating protein expression (10,26). Further studies have reported that miR-411 may function as an oncogene in osteosarcoma, lung and hepatocellular carcinoma tumorigenesis and tumor development (9,11,12,26,27). miR-411 promoted osteosarcoma cell proliferation and migration by inhibiting the expression of the metastasis suppressor protein 1 (MTSS1) (9). Furthermore, high miR-411 expression was an independent poor prognostic indicator for patients with non-small cell lung carcinoma, and compared with healthy

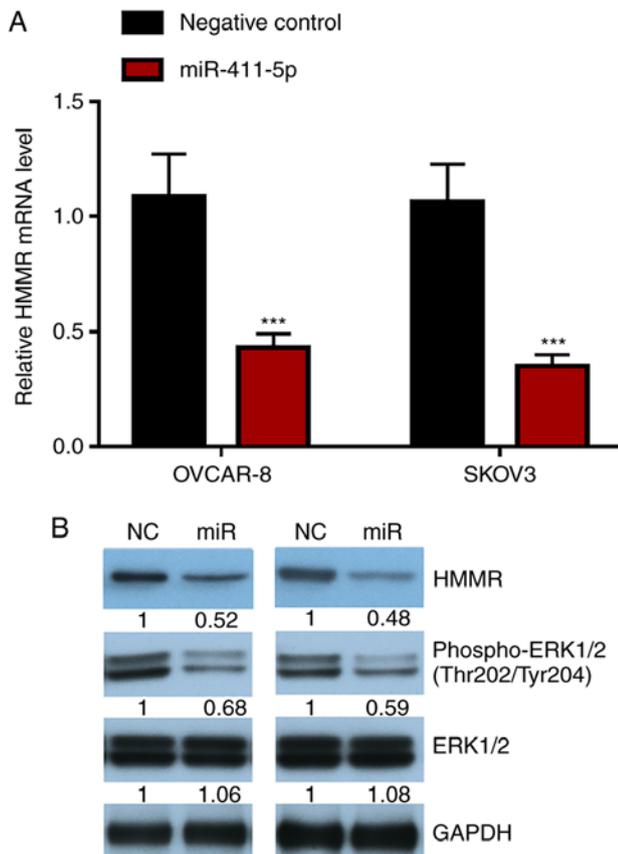

Figure 4. Molecular mechanisms of miR-411-5p in ovarian cancer cells. (B) Western blot analysis of HMMR, phospho-ERK1/2, total ERK1/2 and GAPDH expression in OVCAR-8 and SKOV3 cells 72 h post-transfection with the miR-411-5p mimic. The Student's t-test was used to assess the difference (n=3). Error bars denote the SEM. \*\*\*P<0.001 vs. negative control. miR, microRNA; HMMR, hyaluronan mediated motility receptor; phospho, phosphorylated; NC, negative control.

controls, miR-411 expression levels were higher in the serum of patients with non-small cell lung carcinoma (26). Additionally, other studies have demonstrated that the oncogenic effect of miR-411 on lung cancer cell proliferation was mediated by direct downregulation of forkhead box O1 (10). miR-411 also increased cell migration in lung adenocarcinoma cells, was upregulated in tumors from patients who relapsed systemically and was associated with poor survival time following lung adenocarcinoma resection (11). Another study indicated that miR-411 promotes lung carcinogenesis by directly targeting the tumor suppressor genes sprouty RTK signaling antagonist 4 (SPRY4) and thioredoxin interacting protein (27). Furthermore, it has been reported that miR-411 promoted hepatocellular carcinoma cell proliferation by targeting itchy E3 ubiquitin protein ligase (ITCH) (12).

Alternatively, numerous studies have reported that miR-411 functions as a tumor suppressor in oral, cervical, breast and colorectal cancer, as well as in renal cell carcinoma and glioma (13,14,17,19,20). Recent study has shown that miR-411-5p was downregulated in oral cancer compared with non-cancerous tissue (13). Similarly, miR-411 was significantly downregulated and played a role as a tumor suppressor in renal cell carcinoma (14). In cervical cancer, miR-411 acted

as a potential tumor suppressor to inhibit cancer progression by directly targeting STAT3 (15). Additionally, miR-411-5p inhibited proliferation and metastasis of breast cancer cells by directly targeting growth factor receptor bound protein 2 (GRB2) (17). Zhao *et al* (18) reported that miRNA-411 inhibited malignant biological behaviours of colorectal cancer cells by targeting phosphoinositide-3-kinase regulatory subunit 3 (PIK3R3). Additionally, miR-411-5p decreased glioma cell proliferation by targeting topoisomerase II- $\alpha$  (TOPO2A) (19); overexpression of miR-411-5p inhibited the proliferation of rhabdomyosarcoma cells *in vitro* and tumorigenicity *in vivo* (20); and miR-411-5p activated p38-mitogen activated protein kinase phosphorylation by directly downregulating SPRY4 and promoted apoptosis and myogenic differentiation (20). Furthermore, the miR-379/411 cluster regulated IL-18, significantly suppressed the invasive capacity of MESO1 cells (a tumor model) and contributed to drug resistance in malignant pleural mesothelioma (21).

A number of targets of miR-411 have been reported previously, including MTSS1 (9), TOP2A (19), ITCH (12), STAT3 (15), specificity protein 1 (16), GRB2 (17), PIK3R3 (18), SPRY4 (20), IL-18 (21), hypoxia inducible factor 1- $\alpha$  (28) and matrix metalloprotease-13 (29). In the present study, HMMR was identified as a novel direct target of miR-411-5p by a luciferase reporter assay. HMMR is required for bipolar spindle assembly and mitotic progression by integrating biochemical and structural pathways (30). HMMR expression is associated with poor prognosis and metastasis in non-small cell lung carcinoma (31). Furthermore, upregulation of HMMR in lung adenocarcinoma was associated with an inflammatory molecular signature and poor prognosis (32). Cell surface HMMR is an hyaluronic acid-binding protein that is not highly expressed in normal tissues but is commonly upregulated in a number of advanced forms of cancer (33,34). However, the underlying mechanism of HMMR in ovarian cancer is not completely understood. Using TCGA, the present study suggested that HMMR mRNA expression is higher in ovarian serous cystadenocarcinoma than in normal ovarian tissue.

ERK1/2 kinases are ubiquitous and homologous mitogen activated protein kinases that mediate ligand-stimulated signals for the induction of proliferation, differentiation, survival, apoptosis, angiogenesis and motility (35). Upregulation and elevated activation of ERK1/2 kinases is common in human tumors (36-38). Indeed, studies have reported that in a large number of different types of cancer the ERK1/2 signaling pathway is constitutively active and may be involved in the pathogenesis of these tumors (36-38). Of note, the ERK signaling pathway plays a critical role in ovarian cancer pathogenesis and downregulation of this signaling pathway is highly effective for the inhibition of ovarian tumor proliferation (39). Furthermore, the nuclear localization of phosphorylated ERK1/2 can serve as a marker for the progression of ovarian cancer (39,40).

HMMR is a known modulator of ERK1/2 in certain types of cancer (41,42). HMMR overexpression resulted in activation of the ERK1/2 signaling pathway, which promotes cell proliferation of osteoblastic cells (41). Cell surface HMMR and CD44 act together and coordinate to sustain ERK1/2 signaling, leading to high basal motility of invasive breast

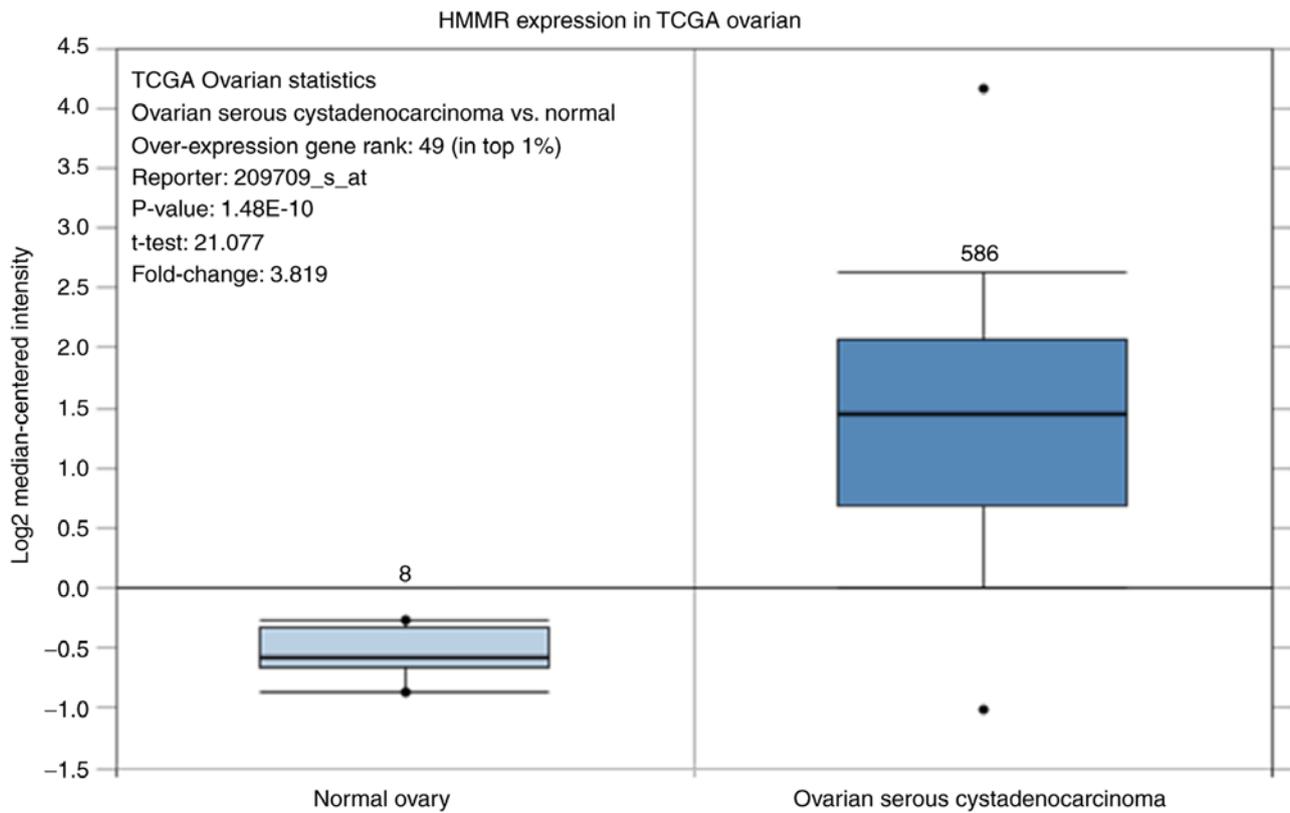

Figure 5. HMMR mRNA differential analysis of paired ovarian serous cystadenocarcinoma and normal tissues. HMMR, hyaluronan mediated motility receptor; TCGA, The Cancer Genome Atlas.

cancer cells (42). The results of the present study suggested that the expression of phosphorylated ERK1/2 and HMMR is decreased following the overexpression of miR-411-5p in ovarian cancer cells, a result that is consistent with the aforementioned studies. The present study suggested a potential interplay between HMMR and ERK1/2, via phosphorylated ERK1/2, which may contribute to cancer cell proliferation and motility modulation.

The present study indicated that the overexpression of miR-411-5p could suppress ovarian cancer cell (OVCA8 and SKOV3) proliferation and motility. In the present study, it was also described that miR-411-5p could downregulate HMMR, which resulted in the downregulation of the ERK1/2 signaling pathway activity, and thus inhibited ovarian cancer cell proliferation and motility. In different cancer types, miR-411-5p may have different roles (12,19). In conclusion, the results of the present study demonstrated that miR-411-5p may be potential therapeutic target for ovarian cancer.

One limitation of the present study was that the results were based on miRNA mimic-mediated overexpression experiments in two ovarian cancer cell lines, where the miRNA level may be much higher than the endogenous miRNA level. Additionally, the wound healing should ideally be performed in 0% FBS, therefore the use of 4% FBS is a minor limitation. Future investigations, in particular *in vivo* experiments, should be performed to confirm the functional mechanisms and investigate the clinical application of miR-411-5p. Collectively, the present study provided a rationale for further investigation into miR-411-5p-based diagnosis, prognosis and targeted therapeutic strategies.
