Abstract. It has been established that excessive apoptosis of nucleus pulposus cells (NPCs) are responsible for pathogenesis of human intervertebral disc degeneration (IDD). The present study aimed to shed light on the molecular mechanisms underlying the protective effects of mesenchymal stem cells (MSCs) on NPCs in an inflammatory environment. NPCs were treated with TNF- α to induce inflammation and then co-cultured with Wharton's Jelly-derived MSCs (WJ-MSCs) without direct interaction. The levels of inflammation markers (IL-1 β , IL-6 and IL-8) in NPCs were detected by performing enzyme-linked immunosorbent assay (ELISA), and expression of metalloproteases and aggrecan, as well as the activity of p38 MAPK pathway were determined through immunoblotting. SB-203580 was used to inhibit p38 signaling, prior to evaluation of the effects of Wharton's Jelly-derived MSCs (WJ-MSCs) on inflammatory response within the co-cultured NPCs. After TNF- α treatment, the levels of inflammatory cytokines, MMP-3, and MMP-13 in NPCs were increased whereas aggrecan was decreased, which was then dramatically reversed by WJ-MSCs co-culture. Likewise, WJ-MSCs suppressed TNF- α -induced phosphorylation of p38 MAPK signaling components including p38, ASK-1, MKK-3 and MKK-6. Blocking p38 MAPK pathway enhanced the anti-inflammatory impact of WJ-MSCs, and there was no significant difference between NPCs co-cultured with WJ-MSCs or the cells cultured alone. WJ-MSCs co-culture

mitigate TNF- α -induced inflammatory response and ECM degeneration in NPCs, the major pathological events are implicated in IDD development, probably by suppressing the p38 MAPK signaling cascade.

Introduction

Low-back pain is a worldwide socio-economic problem that affects more than half the population during their whole life (1,2), and intervertebral disc degeneration (IDD) has been extensively recognized as the most common source of this disorder. Currently, advances in our understanding of the IDD pathogenesis have contributed to the emerging novel therapeutic strategies for retarding the progression or deterioration of it, ranging from pain palliation at early stage to invasive operations at the late stage (3). Unfortunately, these treatment options are not capable of effectively restoring the normal physiological functions of intervertebral disc because of the non-renewable characteristic of nucleus pulposus (NP), one of the major components of intervertebral disc. In addition, surgical interventions for IDD such as spinal arthroplasty and discectomy are usually susceptible to infection and many other complications, hence it is a predominant challenge for spinal surgeons.

IDD is generally characterized by an increase release of pro-inflammatory cytokines, including TNF- α and IL-1 β , which will recruit the activated immune cells into degenerated tissues and further trigger the inflammatory cascade (4). On the other hand, the inflammatory milieu is also responsible for the aberrant activity of MMPs, ADAMTSs and disintegrins, leading to the interruption of ECM homeostasis (5,6) and thus exacerbating the degenerative process. There are increasing number of studies addressing the utilization of mesenchymal stem cells (MSCs) in the treatment of IDD. Previous studies have proved that MSCs differentiate into NP-like cells with elevated expression of NP-related marker genes when co-cultured with nucleus pulposus cells (NPCs) (7). It was also demonstrated that the MSCs could restore the molecular environments of matrix (8), in addition to its capacities of immunomodulation and multilineage differentiation (9). Hitherto, the mechanisms underlying the effect of MSCs on the degenerative process in NPCs and

Key words: mesenchymal stromal cell, intervertebral disc degeneration, p38/MAPK, anti-inflammation

the involved pathophysiological signaling pathways have not been fully described.

Herein, the effect of MSCs on inflammatory response within NPCs was evaluated after exposure to pro-inflammatory cytokine stimulation, and the pathophysiological pathways that may be involved were also investigated. Our results provide insights into the mechanisms underlying the effects of MSCs on TNF- α -induced inflammatory response in NPCs, which will further facilitate the application of stem cells in the therapy for the degenerative process.

Materials and methods

NPCs isolation and culture. The nucleus pulposus samples were collected from patients undergoing surgery from Jan 2016 to May 2018. The magnetic resonance classification of IDD was performed according to a previous report (10). Written informed consents were obtained from patients and counterparts and all the experimental protocols were approved by the Ethic Committee of Honghui Hospital affiliated to Xi'an Jiaotong University (approval no. 2019-12).

The NP tissues were dissected into pieces of 1.0 mm³ and digested with 0.25% protease at 37°C for 1 h, followed by 0.2 mg/ml of collagenase type II for 4 h, prior to filtration through a sterilized mesh with 70- μ m pore size and centrifugation at 300 x g, at 4°C for 5 min. Cells were resuspended and maintained in DMEM/F12 medium (Gibco; Thermo Fisher Scientific, Inc.) supplemented with 10% fetal bovine serum (FBS) and 1% penicillin-streptomycin (Sigma-Aldrich; Merck KGaA) at 37°C in 5% CO₂. The medium was replaced every 2-3 days and the primary culture was sub-cultured when cells grew to ~80% confluence. NPCs were incubated with 10 ng/ml TNF- α (Sigma-Aldrich; Merck KGaA) or equal amount of DMEM medium as a negative control for 24 h before further assessment.

Isolation and culture of Wharton's Jelly-derived MSCs (WJ-MSCs). The fresh umbilical cord was obtained from in a full term neonate, followed by being washed with pre-cold PBS to remove the blood clot. Afterwards, the Wharton's jelly was isolated from umbilical cord and cut into 1 mm³ fragments, which were incubated with type II collagenase (0.2 mg/ml, Sigma-Aldrich; Merck KGaA) at 37°C for 18 h and then digested using 2.5% trypsin for 30 min with agitation. Finally, the cells were fixed with 2 ml FBS for 2 h and then maintained in 8 ml of L-DMEM medium (HyClone; GE Healthcare Life Sciences) containing 1% penicillin-streptomycin, 50 μ g/ml L-ascorbic acid and 2 mM glutamine at 37°C in a humidified atmosphere of 5% CO₂. The culture medium was replaced every 2 days. The cells were passaged when the confluence reached 80-90%. WJ-MSCs from passage 3 were used for determination of cell surface antigens. The identification of MSCs is illustrated in Fig. 1 and MSCs differentiate into NP-like cells, with elevated expression of NP-related marker genes, when co-cultured with NPCs.

Enzyme-linked immunosorbent assay (ELISA). The content of released proteins in cell culture supernatant was measured using specific ELISA kits (R&D Systems). Briefly, the wells of a high protein binding 96-well plate (Corning Costar, Inc.)

were coated overnight with 2 ng of monoclonal antibody against IL-1 β , IL-6 or IL-8. Wells were then washed 4 times with PBS and blocked for at least 1 h with PBS containing 10% FBS, followed by the addition of clear cell supernatants and standard dilutions of recombinant human IL-1 β , IL-6 or IL-8, prior to 2-h incubation at 37°C. After washing thoroughly with a buffer containing PBS and 0.05% Tween-20, each well was incubated with biotinylated antibody for 60 min and then washed 3 times. After staining with streptavidin-HRP for 30 min, substrate working solution was added to each well and incubated for 15-20 min in the dark. The reaction was then stopped by the addition of 100 μ l of 2 M H₂SO₄, and the OD₄₅₀ was measured with an ELISA plate reader (Model 550; Bio-Rad Laboratories, Inc.). Each experiment was independently repeated at least three times.

Western blotting. Primary polyclonal antibodies against human p-p38, p38, ASK-1, MKK-3, MKK-6, MMP-3, MMP-13, aggrecan, and actin were purchased from Abcam. Proteins were extracted from NP tissues or cell lysates with RIPA lysis buffer supplemented with protease inhibitors and phosphorylase inhibitor. The protein concentration was measured using the BCA assay (Pierce) following the manufacturer's instructions. The total proteins were resolved by 10% sodium dodecyl sulfate polyacrylamide gel electrophoresis (SDS-PAGE) before being transferred to polyvinylidene fluoride (PVDF) membrane, which were blocked with 5% silk milk for at least 1 h and incubated overnight at 4°C with specific primary antibodies (1:1,000 diluted). After rinsing with TBST, the membrane was incubated for 1 h at room temperature with HRP-conjugated goat anti-rabbit IgG (1:3,000 diluted). Finally, the labeled proteins were visualized with ECL substrates (EMD Millipore) before quantitative analysis using AlphaView software (ProteinSimple). Each experiment was independently repeated at least three times.

Co-culture of WJ-MSCs and NPCs. For co-culture without direct cell-cell contact, NPCs (1x10⁶ cells/well) were seeded on the bottom of transwell 6-well plates, and WJ-MSC cells were placed onto the apical compartment of a 6-well polyester track-etched cell culture insert with a membrane pore size of 0.4- μ m (Thermo Fisher Scientific, Inc). Sequentially, cells were grown in DMEM/F12 medium at 37°C in a humidified atmosphere of 5% CO₂. NPCs were cultured on common plates as a control and subjected to further analysis.

Statistical analysis. Data are presented as means \pm standard deviation (SD). All *in vitro* experiments included at least 3 replicates per group. Groups were compared using the two-tailed Student's t-test for parametric data. All statistical analyses were carried out using SPSS 19.0 software (IBM Corp.). P<0.05 was considered to indicate a statistically significant difference.

Results

WJ-MSCs suppress TNF- α -induced inflammation response in NPCs. Pro-inflammatory cytokine TNF- α was used to mimic the inflammatory milieu of IDD, and the expression profiles of several inflammation markers in NPCs were evaluated.

Figure 1. Identification of human WJ-MSCs. (A) Representative image of WJ-MSC spindle-like morphology and adherence to plastic (scale bar, 50 μ m). (B) Cell surface markers (CD73, CD90, CD105, CD34, CD45 and HLA-DR) of MSC were tested by flow cytometric analysis. (C) The relative expression levels of gene markers of NP cells were detected in co-cultured WJ-MSCs by qRT-PCR. * $P < 0.05$ compared to gene expression in MSCs cultured alone. WJ-MSCs, Wharton's Jelly-derived MSCs; MSCs, mesenchymal stem cells.

As shown in Fig. 2A, the levels of IL-1 β , IL-6 and IL-8 were dramatically increased upon TNF- α stimulation. We also observed remarkable augment in the expression of MMP-3 and MMP-13. Inversely, aggrecan level synthesized by NPCs was significantly declined after cytokine treatment (Fig. 2B), suggestive of aggrecan fragmentation and breakdown of hydrated ECM within the nucleus.

TNF- α -treated NPCs were co-cultured with WJ-MSCs to determine the effect of WJ-MSCs on the intracellular inflammatory response and the involved signaling transduction. As displayed in Fig. 2A, WJ-MSCs evidently compromised the increased production of IL-1 β , IL-6 and IL-8 by NPCs. In fact, there was no significant difference in the expression of these markers within MSCs, in the presence and absence of TNF- α stimulation (data not shown). Additionally, expression levels of both MMP-3 and MMP-13 were suppressed in NPCs that co-cultured with WJ-MSCs in comparison to cells exposed to

TNF- α alone, whereas aggrecan production was elevated in the presence of WJ-MSCs (Fig. 2B). Therefore, WJ-MSCs can ameliorate inflammatory status within the co-cultured NPCs without direct contact.

WJ-MSCs inhibit p38 MAPK signaling transduction activated by the inflammatory milieu. Following TNF- α stimulation, the phosphorylation of apoptosis signal regulating kinase-1 (ASK-1) was significantly enhanced (Fig. 3). Moreover, the MAPK kinases including MKK-3 and MKK-6 were also activated after incitement by the pro-inflammatory cytokine TNF- α , hence promotion of p38 phosphorylation. The above indicate that the p38 MAPK signaling was activated, which might contribute to the promotion of inflammatory responses during the degenerative process.

Notably, the phosphorylated forms of the above-mentioned molecules implicated in p38 MAPK pathway were found

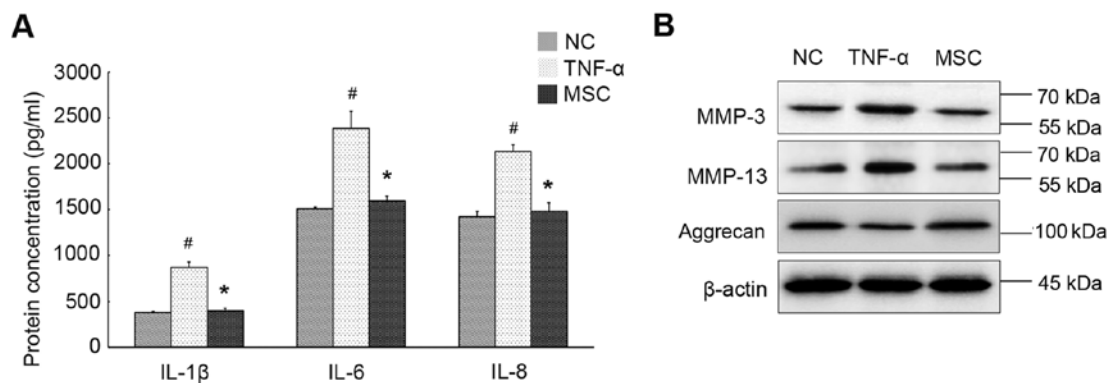

Figure 2. WJ-MSCs suppress TNF- α -induced inflammation response in NPCs. (A) ELISA was performed to determine the levels of IL-1 β , IL-6 and IL-8 secreted by NPCs that were subjected to different treatments. (B) The protein level of MMP-3, MMP-13, and aggrecan by NPCs was evaluated using western blot assay after different treatments. [#]P<0.05 compared to the NC group; ^{*}P<0.05 compared with the TNF- α stimulation alone. Figure 3. WJ-MSCs inhibit TNF- α -induced activation of p38 MAPK signaling. The phosphorylation of ASK-1, p38, MKK-3 and MKK-6 were measured using western blot assay to assess the activities of the corresponding pathways. WJ-MSCs, Wharton's Jelly-derived MSCs; MSCs, mesenchymal stem cells.

decreased due to indirect co-culture between NPCs and WJ-MSCs, suggesting that WJ-MSCs may exert the protective role by virtue of the activation of p38 MAPK pathway.

WJ-MSCs suppress TNF- α -induced inflammation by inhibiting p38 MAPK signaling. To verify this observation, p38 MAPK signaling inhibitor SB-203580 was utilized and, as expected, it was found that this led to an obvious decrease in the phosphorylation forms of p38 (Fig. 4). Although TNF- α -induced MMP-3 and MMP-13 was decreased due to WJ-MSC co-culture, their levels synthesized by NPCs that were co-cultured with WJ-MSCs were further reduced in the presence of SB-203580, whereas aggrecan showed the opposite results. Furthermore, when cells were treated with SB-203580, NPCs co-cultured with WJ-MSCs showed no significant difference from those cultured alone, which suggested that blockage of p38/MAPK pathway protected NPCs against ECM breakdown, regardless of the analogous function of WJ-MSCs. Considering IL-1 β , IL-6 and IL-8 protection, NPCs exposed to SB-203580 displayed values lower than those observed in the co-cultured

cells devoid of SB-203580. Also there was barely detectable difference between NPCs cultured alone and the co-cultured cells when they were subjected to SB-203580 treatment. Thus, we concluded that WJ-MSCs might suppress TNF- α -mediated inflammation in NPCs by partially inactivating p38/MAPK signaling.

Discussion

Not until recently have MSCs been introduced into the therapeutic managements of IDD, emerging as a promising strategy from bench (11-13) to bedside (14). MSCs are probably implicated in the degenerative disc repair in the following aspects: i) complement damaged cells through regeneration of disc-specific cells that have the ability to produce ECM components; ii) control the inflammatory response and (iii) promote tissue regeneration by virtue of paracrine signaling factors (15).

Multiple types of tissues are currently proposed as source of MSCs, and among them adipose tissue and bone marrow are predominantly used in IDD-related research. Owing to limited stemness properties and invasive harvesting procedure, MSCs derived from both tissues are restricted in practice (16-19). Herein, WJ-MSCs were introduced in the present study which attempted to provide novel insight into the molecular mechanisms underlying how MSCs play their role in the therapies of IDD disease.

The mitogen-activated protein kinase (MAPK) plays a pivotal role in mediating many cellular processes including responses to inflammation, damage or stress, and cell differentiation. In particular, the implication of p38 MAPK signaling cascades in the pathogenesis of IDD is gradually revealed. By blocking the p38 MAPK pathway, Studer *et al* (20) found that p38 MAPK was linked to the increased synthesis of inflammation- and pain-related prostaglandin E2 (PGE2) and IL-6, as well as the aggrandized ratio of MMP-3 to TIMP-1. Various stimuli accelerate the breakdown of ECM or inflammation through the activation of p38 MAPK signaling (20-22). In addition, p38 MAPK participate in the regulation of cell senescence of NPCs within the degenerative disc tissue (23). Our results demonstrated that p38 MAPK was initiated upon TNF- α stimulation mimicking the inflammatory microenvironment

Figure 4. Blocking the p38 MAPK signaling enhances the protective effects of WJ-MSCs. (A) The expression alterations of MMP-3, MMP-13 and aggrecan induced by TNF- α were assessed by immunoblot assay in the presence or absence of SB-203580. (B) The levels of inflammation markers were evaluated via ELISA. ns, not significant; [#]P<0.05 compared to the NC group; ^{*}P<0.05. within IDD, but p38 MAPK and the upstream signaling in NPCs were suppressed when co-cultured with WJ-MSCs. This indicated that WJ-MSCs might exert the effects on inflammatory response through inhibition of p38 MAPK pathway.

Given that MSCs and NPCs were co-cultured without cell-cell interaction, it was suggested that MSCs modulate local inflammatory milieu via paracrine signaling transduction. Afterwards, p38/MAPK inhibitor SB-203580 was utilized and it resulted in an obvious decrease in the TNF- α -induced synthesis of inflammatory markers. Considering MMP-3 and MMP-13, NPCs exposed to SB-203580 displayed values lower, whilst a higher amount of aggrecan, than those observed in absence of SB-203580. Inactivation of p38 MAPK pathway can protect NPCs against the detrimental inflammatory response, which is strictly consistent with previous studies. Intriguingly, once cells were pre-treated with SB-203580, levels of all these proteins expressed in NPCs co-cultured with WJ-MSCs were analogous to those NPCs cultured alone, suggesting that blocking p38 MAPK enhanced the protective actions of WJ-MSCs in suppressing inflammatory response. Co-culture with WJ-MSCs might have impact on other signaling pathways that interplay with p38 MAPK during this process. Once p38 MAPK signaling was blocked, there was barely detectable difference between NPCs co-cultured with WJ-MSCs and the cells cultured alone. That is, p38 MAPK signaling plays a predominant role in this process, and WJ-MSCs potentially suppress the TNF- α -mediated inflammation within NPCs in a p38 MAPK-dependent manner.

In conclusion, our data demonstrate that after co-culture with WJ-MSCs, TNF- α -induced inflammatory response in NPCs was significantly diminished, and the activities of p38 MAPK and the related upstream pathways were decreased, indicating an inhibitory effect of WJ-MSCs on inflammation as well as ECM degeneration by suppressing p38 MAPK activation. Furthermore, blocking p38 MAPK pathway markedly further enhanced the applaudable performance of WJ-MSCs in anti-inflammation, which suggested that WJ-MSCs mitigated

the degenerative process within disc tissue by predominantly inactivating p38 MAPK signaling pathway. These findings highlight a possible mechanism underlying the role of MSCs in meliorating the inflammatory milieu within degenerated NPCs, which may be applicable to MSCs-based therapy for disc degeneration.
