Jinan University, Guangzhou, Guangdong 510630, P.R. China

Abstract. Centromere coiled-coil protein 110 (CCP110) plays a role in the development of several types of cancer; however, its regulatory mechanism and role in endometrial cancer is unclear. The present study revealed that CCP110 is regulated by a signaling pathway involving microRNA (miR/miRNA)-129-2-3p and the long non-coding RNA (lncRNA) X-inactive-specific transcript (XIST), and plays a role in controlling the proliferation, migration and invasion of endometrial cancer cells. CCP110 was upregulated in human endometrial cancer tissues, as revealed by immunohistochemistry, and high expression of the protein was related to reduced overall survival of the patients. Genetic knockdown of CCP110 by small interfering RNA promoted apoptosis and suppressed the proliferation, migration, invasion and colony formation of endometrial cancer cells significantly in the endometrial cancer Ishikawa and HEC-1B cell lines, as assessed by flow cytometry, and Cell Counting Kit-8, Transwell and colony formation assays. A bioinformatics analysis and luciferase reporter assay revealed that CCP110 is a target of miR-129-2-3p. Overexpression of miR-129-2-3p mimic fragments inhibited the proliferation, migration and invasion of endometrial cancer cells significantly, while co-overexpression of CCP110 counteracted these inhibitory effects. The expression level of the lncRNA XIST was upregulated significantly in endometrial cancer tissues, as assessed by reverse transcription-quantitative PCR assay, while that of miR-129-2-3p was downregulated significantly. A bioinformatics analysis and luciferase reporter assay showed that XIST could inhibit miR-129-2-3p via a miRNA sponge effect. Furthermore, co-overexpression of XIST antagonized the inhibitory effect of the miR-129-2-3p mimic on the luciferase reporter gene signal and protein expression of CCP110. Co-overexpression of XIST also abolished the inhibitory effect of the miR-129-2-3p mimic on the proliferation, migration and invasion of endometrial cancer cells. Overall, these data identified a novel regulatory mechanism of CCP110 involving XIST and miR-129-2-3p, which affected the development of endometrial carcinoma. CCP110, XIST and miR-129-2-3p could represent novel targets for the clinical treatment of endometrial cancer.

Introduction

Endometrial carcinoma/cancer (EC) is a common reproductive system malignancy in menopausal and perimenopausal women, ranking fourth for incidence among female malignant tumors in developed countries (1). The incidence of EC has increased in recent years, threatening the health of women globally (2,3). Once EC has progressed to an advanced stage, the 5-year survival rate is low (4-6). Early-stage EC is rarely found by physical examination, as once the uterus or its appendages are palpated with abnormal masses, they are generally in the advanced stage of EC (7,8). The occurrence and development of EC is a result of the interaction of environmental factors and genetic variation, involving a series of components such as differential expression of various genes and transcription factors, abnormal regulation of cell signal transduction pathways and imbalance of the cellular microenvironment homeostasis (9,10). Different pathological changes and molecular features determine the risk level and prognosis of patients with EC (11). To date, the molecular mechanisms regulating the tumorigenesis, development and metastasis of EC have not been elucidated fully. Identifying these mechanisms is important for the identification of key therapeutic targets.

Centrosome amplification, resulting in multiple centrosomes, occurs frequently in EC cells (12). This process can promote the growth of several tumors by inducing chromosome mis-segregation and regulation of the microtubule cytoskeleton, resulting in enhanced directed migration and invasion of malignant cells (13). Centromere coiled-coil protein 110 (CCP110, also known as CP110) is an evolutionarily conserved protein that is important for centrosome function (14,15).

*Contributed equally

Overexpression of CCP110 leads to centrosome expansion and increases the invasive phenotype of cells (14,16). CCP110 is involved in docetaxel-induced drug resistance of breast cancer cells (17) and mediates metastasis in prostate cancer (18). In addition, inhibition of cyclin-dependent kinase 2 can downregulate CCP110 expression, causing anaphase catastrophe and inhibiting lung cancer cell growth (19). However, to the best of our knowledge, the role of CCP110 in the tumorigenesis and development of EC has not yet been reported.

MicroRNAs (miRNAs/miRs) are a class of evolutionarily conserved, non-coding, single-stranded small RNAs (~22 nucleotides) that can degrade or inhibit the translation of target mRNAs via specific binding (20,21). MiRNAs regulate cell proliferation, differentiation and apoptosis by controlling the expression of certain signaling molecules, including transcription factors, cytokines, growth factors and pro-apoptotic and anti-apoptotic genes (22). Increasing numbers of miRNAs have been shown to play important roles in EC (23-25). Next-generation sequencing and miRNA screening technologies have revealed that several miRNAs are differentially expressed between EC and normal endometrial cells (25). For example, miR-103, -106a, -107, -185 and -429 are upregulated in EC and are involved in tumorigenesis, invasion and metastasis, whereas miR-30c, -152, -193 and -221 are downregulated in EC (26,27). These miRNAs participate in various cell signaling pathways by targeting downstream genes and play a regulatory role in the proliferation, migration, invasion and apoptosis of EC cells (28,29). MiR-129 also reportedly plays a role in EC (30,31).

Long non-coding RNAs (lncRNAs) are defined as RNA molecules that exceed 200 nucleotides and are not translated into proteins (32). These RNAs can regulate the expression of target genes by participating in epigenetic, transcriptional and post-transcriptional pathways, and are related to the proliferation, migration and invasion of various tumors, such as female reproductive or gynecological cancers (33,34). Notably, abnormally expressed lncRNAs play an important role in the development of EC (35-37). X-inactive-specific transcript (XIST), one of the first lncRNAs to be discovered, is located at the X inactivation center of chromosome Xq13.2 and plays a prominent role in X inactivation (38). XIST is involved in the occurrence and development of several disorders, including pulmonary fibrosis, inflammation, neuropathic pain, cardiomyocyte hypertrophy and osteoarthritic chondrocyte differentiation (39). It also plays an important regulatory function in various types of cancer, and can be used as a diagnostic. It can also function as a prognostic biomarker and potential therapeutic target for brain tumors, leukemia and lung, breast and liver cancer (40). There are few reports of the involvement of XIST in EC and the detailed mechanism remains to be determined, and thus, this was investigated in the current study.

The present study examined the expression levels of CCP110, XIST and miR-129-2-3p in human EC tissues and cell lines, and explored the targeting relationship between these species and their functional roles in the proliferation, migration and invasion of EC cells.

Materials and methods

Ethical statements and tissue samples. A total of 19 female patients (age range, 37-77 years; mean age, 55.58±10.26 years) with EC who underwent surgical excision at the First Affiliated Hospital of Jinan University (Guangzhou, China) were enrolled in the study between March 2006 and May 2008. Inclusion criteria: Patients had been admitted to the hospital for the first time and did not receive any malignant tumor treatments, such as chemotherapy or radiotherapy, before surgery; postoperative tissues were diagnosed by pathologists as EC with parallel International Federation of Gynecology and Obstetrics staging; patients were aware of and agreed to the whole process of the study; and patient clinical data and follow-up data were complete and available. Exclusion criteria: Patients with other malignant tumors; patients with immune system diseases or infectious diseases; and patients with severe impairment of the heart, liver, kidney and other organ functions. EC tumor samples and adjacent non-tumor tissues (distance from cancer tissue >2 cm) were collected immediately after the excision and were frozen quickly in liquid nitrogen (-320˚F). For the analysis of overall survival, follow-up of all patients was carried out for at least 8 years.

Immunohistochemistry (IHC). For IHC assay, tissue sections (5-μm) were deparaffined, rehydrated, and incubated for 1 h at 80˚C in citrate buffer (10 mM; pH 6.0) with 0.05% Tween 20 for antigen retrieval. After saturation for 30 min with 1% BSA (cat. no. #ST023-50g; Beyotime Institute of Biotechnology) in PBS at room temperature, the sections were incubated with CCP110 antibody (1:1,000; cat. no. ab99337; Abcam) overnight at 4˚C, followed by incubation with biotin-linked anti-rabbit IgG (cat. no. #E043201-6; 1:1,000; Agilent Technologies, Inc.) for 1 h at room temperature and then with the ABC complex (cat. no. #ab8647; Abcam) at 37˚C for 20 min. IHC scores were determined as follows: Cells with <10% staining were scored as negative staining (-, 1); 10-49% staining as (+, 2); 50-74% staining as (++, 3); 75-100% staining as (+++, 4). The staining color was scored as light-yellow particle (score 1), brown-yellow particle (score 2) and brown particle (score 3). Number score times the color score was used as the final score (41). A score value ≤5 was grouped as low expression, while a score >5 was grouped as high expression.

Cell culture and transfection. The HEC-1B and Ishikawa human EC cell lines were procured from the Cell Bank of Type Culture Collection of The Chinese Academy of Sciences. Both cell lines were cultured in RPMI 1640 medium (Invitrogen; Thermo Fisher Scientific, Inc.), supplemented with 10% FBS (cat. no. #10270-106; Gibco; Thermo Fisher Scientific, Inc.) and 100 U/ml penicillin and streptomycin (cat. no. #15140122; Gibco; Thermo Fisher Scientific, Inc.) and were maintained at 37˚C in a humid atmosphere containing 5% CO_2.

The *CCP10* and *XIST* genes were cloned and inserted into the pcDNA3.1 vector (cat. no. XY8014; Xinyu Biology) The small interfering RNA (siRNA) targeting *CCP110* (siCCP110), non-targeting negative control (NC) siRNA, miR-129-2-3p mimics, miR-129-2-3p inhibitors, NC mimic, and NC inhibitor were synthesized by Shanghai GenePharma Co., Ltd. For transfection, Lipofectamine® 2000 (cat. no. #11668027; Invitrogen; Thermo Fisher Scientific, Inc.) was used according to the manufacturer's instructions with >1.3 μg nucleic acid. Cells were harvested 48 h after transfection for total RNA or protein isolation. The oligonucleotide sequences were as

follows: NC, 5'-CCCACCAGUUUGAGACUCCACAAAU-3'; siCCP110, 5'-AAGACGUUCCAGGACAUCAUC-3'; miR-NC, 5'-UUGUCCGAACGUGUCACGUTT-3'; miR-129-2-3p mimics, 5'-AAGCCCUUACCCCAAAAAGCAU-3'; miR-NC inhibitor, 5'-CACUACUUUUGUGUAGUACAA-3'; miR-129-2-3p inhibitors, 5'-AUGCUUUUUGGGGUAAGG GCUU-3'.

Reverse transcription-quantitative PCR (RT-qPCR). Total RNA was isolated from tissues or cells using TRIzol® reagent (Invitrogen; Thermo Fisher Scientific, Inc.), according to the manufacturer's instructions. EasyScript cDNA Synthesis SuperMix (cat. no. #AE301-02; Beijing Transgen Biotech Co., Ltd.) was used for reverse transcription of miRNA, according to the manufacturer's instructions. The RT-qPCR analysis was performed using the LightCycler FastStart DNA MasterPlus SYBR Green I kit (Roche Diagnostics), as per the manufacturer's instructions. The following primers were used: Human *CCP110* (NM_001323570.2; forward, 5'-AGAGGT GGAGTCGGGGTGGCAG-3'; reverse, 5'-CCCGCCATATTA CGGATCTCAGGCT-3'); actin (forward, 5'-TCACCCACA CTGTGCCCATCTACGA-3'; reverse, 5'-CAGCGGAACCGC TCATTGCCAATGG-3'), miR-129-2-3p (MIMAT0004605; forward, 5'-TTCCAAGCCCTTACCCCA-3'; reverse, 5'-CAC TTCCTCAGCACTTGTTCCTAT-3'), XIST (NR_001564; forward, 5'-TCAGCCCATCAGTCCAAGATC-3'; reverse, 5'-CCTAGTTCAGGCCTGCTTTTCAT-3') and U6 (forward, 5'-CTCGCTTCGGCAGCACA-3'; reverse, 5'-AACGCTTCA CGAATTTGCGT-3'). Conditions for PCR were as follows: 1 cycle of 94˚C for 3 min and 38 cycles of 94˚C for 20 sec, 60˚C for 30 sec and 68˚C for 30 sec. The expression level of miR-129-2-3p was normalized to that of *U6*, whereas those of XIST and *CCP110* were normalized to the expression level of actin, using the $2^{-\Delta\Delta Cq}$ method (42). All PCRs were repeated at least three times.

Cell Counting Kit-8 (CCK-8) assay. Adherent cells in the logarithmic growth phase were trypsinized and counted, and an appropriate number of cells were seeded into 96-well plates (in triplicate) and cultured at 37˚C for 24 h. After treatment with miR-129-2-3p mimics and inhibitors (or the negative controls) for various time points (0, 24, 48, 72 and 96 h), the cells were incubated with 10 µl of CCK-8 reagent (Dojindo Molecular Technologies, Inc.) for 1 h, and then the absorbance was measured at 450 nm to evaluate cell proliferation.

Transwell cell migration and invasion assay. Cell migration and invasion were examined via a Transwell assay (Corning Inc.). Briefly, cells were trypsinized and counted, and then $1x10^5$ cells were resuspended in serum-free culture medium (RPMI 1640 medium) and seeded into the upper chamber of a Transwell plate (6.5-mm insert with a 8-µm pore size polycarbonate membrane). The lower chamber was loaded with culture medium (RPMI 1640 medium) containing 20% FBS. After 24 h of culture at 37˚C, cells that had migrated into the lower chamber were fixed with 100% methanol for 10 min at room temperature and stained with 0.1% crystal violet for 10 min at room temperature. The cells were then observed using an inverted microscope with bright field and five random fields were counted. For the invasion assay, the chamber was

paved with a layer of Matrigel (BD Biosciences) at 2.5 mg/ml at room temperature for 4 h before cell culture.

Cell colony formation assay. Ishikawa and HEC-1B cells were trypsinized and resuspended, then 2,000 cells were seeded into six-well plates in triplicate and cultured in a humidified atmosphere containing 5% CO_2 at 37˚C for 14 days. Subsequently, the cell colonies were washed with PBS, fixed for 30 min with 100% methanol, and stained for 20 min with 0.1% crystal violet (1 mg/ml; Beyotime Institute of Biotechnology) at room temperature. One colony means a visible staining spot counted by the naked eye. The mean colony numbers were then calculated. A colony was a staining spot visible to the naked eye.

Flow cytometry assay. To detect apoptosis, EC cells were stained with the Annexin V-FITC/PI Dual Staining kit (cat. no. #640914; Biolegend, Inc.) and then subjected to flow cytometric analysis. Briefly, cells were digested by 0.5% trypsin at 37˚C for 2 min and then a 100 µl aliquot of the cell suspension was transferred to a microcentrifuge tube and mixed with 5 µl of Annexin V-FITC (1 mg/ml) and 5 µl of propidium iodide (2.5 mg/ml). The sample was then vortexed for 10 sec at room temperature and incubated for 15 min at room temperature in the dark. Subsequently, binding buffer (400 µl) was added and the samples were analyzed using BD FACSDiva software 7.0 (BD Biosciences).

Western blotting. Tissues or cells were lysed with RIPA lysis buffer (cat. no. #P0013C; Beyotime Institute of Biotechnology). The concentration of proteins was determined by BCA kit (cat. no. #P0012; Beyotime Institute of Biotechnology). The proteins (30 µg in each lane) were separated using 10% SDS-PAGE and transferred to PVDF membranes (cat. no. #IPVH00010; MilliporeSigma). The membranes were blocked with 5% skimmed milk solution at room temperature for 1 h and then incubated with the following primary antibodies at 4˚C overnight: Anti-CCP110 (1:1,000; cat. no. ab99337; Abcam) and anti-GAPDH (1:2,000; cat. no. ab8245; Abcam). Subsequently, the membranes were incubated with goat anti-rabbit (cat. no. #A0208) and anti-mouse (cat. no. #A0216) HRP-conjugated secondary antibodies (1:1,000; Beyotime Institute of Biotechnology) at room temperature for 1 h, and blots were visualized using an ECL kit (cat. no. #P0018S; Beyotime Institute of Biotechnology). The gray density was determined by ImageJ Version 1.50 (National Institutes of Health) and the CCP110 signal was normalized to that of the loading control (GAPDH). Each experiment was performed at least three times.

Bioinformatics analysis and dual-luciferase reporter assay. Potential binding sites for miR-129-2-3p and CCP110/XIST were predicted using the TargetScan (43), miRDB (44), StarBase (45) and picTar (46) online software packages. The 3' UTR fragments of *CCP110* and XIST containing potential binding sites for miR-129-2-3p were cloned into the pGL3 vector (Promega Corporation) to construct wild-type (WT) and mutant (MUT) reporter vectors. The vectors were then co-transfected by Lipofectamine 2000 (Thermo Fisher Scientific, Inc.) with the miR-129-2-3p mimics or miR-NCs (as aforementioned) into EC cells. Cells were collected 48 h
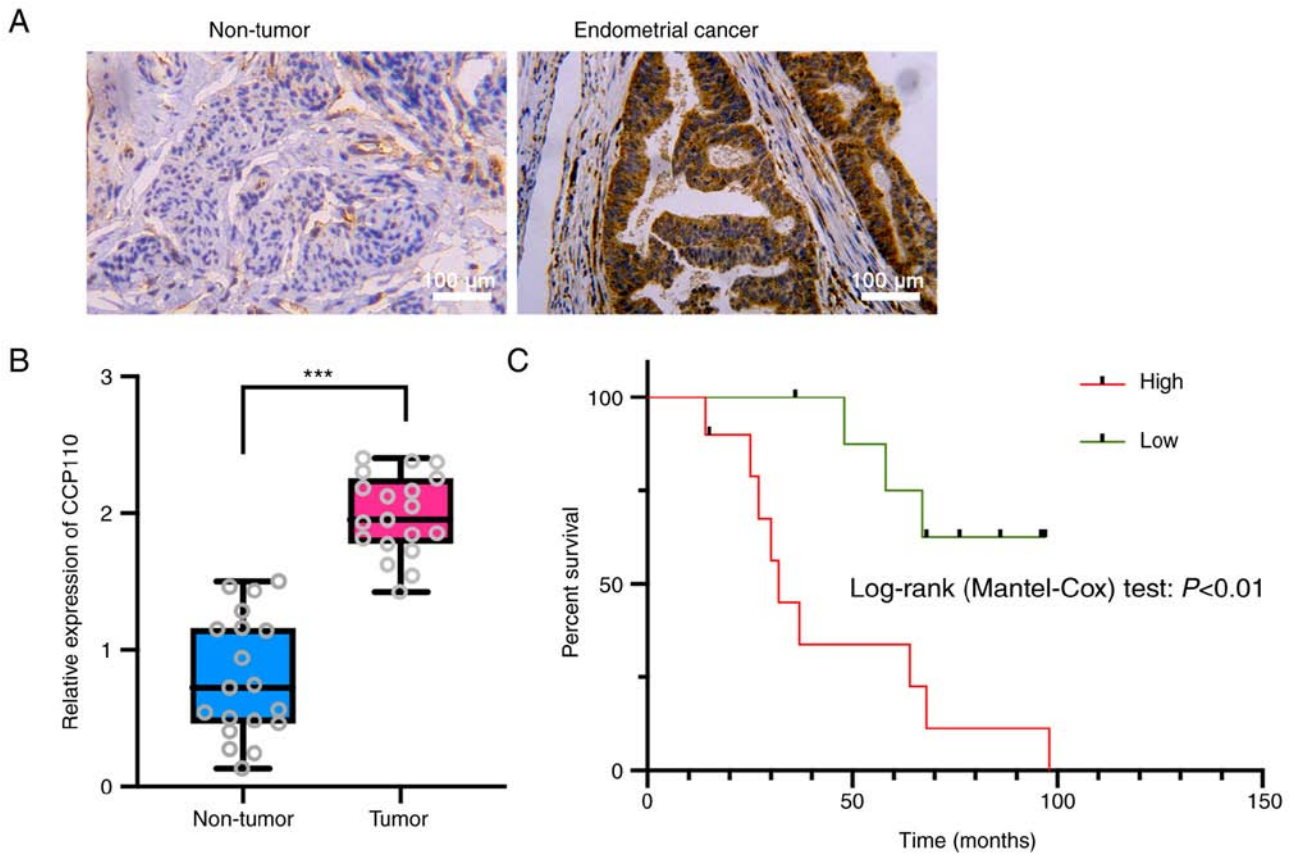

Figure 1. CCP110 is upregulated in EC tissues and is associated with a poor prognosis of patients with EC. (A) EC tissues and paracancerous tissues were collected from 19 patients and immunohistochemical experiments were performed to detect CCP110. Scale bar, 100 μm. (B) Quantified immunohistochemistry data. (C) Kaplan-Meier survival analysis according to the expression level of CCP110 in EC. ***$P<0.001$. CCP110, centromere coiled-coil protein 110; EC, endometrial carcinoma/cancer.

later and the luciferase activity was determined using a dual-luciferase reporter assay system (Promega Corporation). The activity of firefly luciferase was normalized to that of *Renilla* luciferase.

Statistical analysis. The data are presented as the mean ± standard deviation and the statistical analysis was performed using SPSS version 16 (SPSS Inc.). Kaplan-Meier survival curves were used to analyze the relationship between the expression levels of miRNA-129-2-3p and the overall survival of the patients. Differences between two groups or among multiple groups were analyzed using Student's t-test (paired for tissue analysis and unpaired for the others) or one-way ANOVA (with Tukey's post hoc test where appropriate), respectively. The expression between cancer tissue and adjacent normal tissue was compared using a non-parametric Wilcoxon signed rank test. Spearman's rank correlation coefficient was used to measure the statistical dependence between two variables. Kaplan-Meier and log rank tests were used to analyze the survival curve. $P<0.05$ was considered to indicate a statistically significant difference.

Results

CCP110 is upregulated in EC. Cancerous and paracancerous tissues were collected from 19 patients with EC and the expression level of CCP110 was detected using immunohistochemistry. CCP110 expression was significantly upregulated in cancer tissues compared with adjacent tissues (Fig. 1A and B), and the overall survival of patients with high CCP110 expression was significantly shorter compared with that of patients with low CCP110 expression (Fig. 1C). These findings suggested that CCP110 was a carcinogenic factor that affected the prognosis of patients with EC.

Genetic knockdown of CCP110 induces apoptosis and suppresses the development of EC cells. To examine the role of CCP110 in EC further, the Ishikawa and HEC-1B EC cell lines were transfected with a NC siRNA or a siRNA targeting CCP110 (siCCP110). The expression of the protein was measured using western blotting. Compared with the NC, treatment of both cell lines with siCCP110 inhibited expression of the CCP110 protein significantly (Fig. 2A and B and Fig. S1). CCK-8 and Transwell assays showed that knockdown of CCP110 significantly suppressed the proliferation, migration and invasion of both cell lines (Fig. 2C-G). In addition, a colony formation assay revealed that treatment with siCCP110 significantly inhibited the colony formation ability of both cell lines (Fig. 2H and I). Next, flow cytometry assay was used to examine apoptosis, which revealed that silencing of CCP110 significantly upregulated the apoptosis rate in both cell lines (Fig. 2J and K). Overall, these results indicated that genetic knockdown of CCP110 induced apoptosis and suppressed the growth, migration and invasion of EC cells.
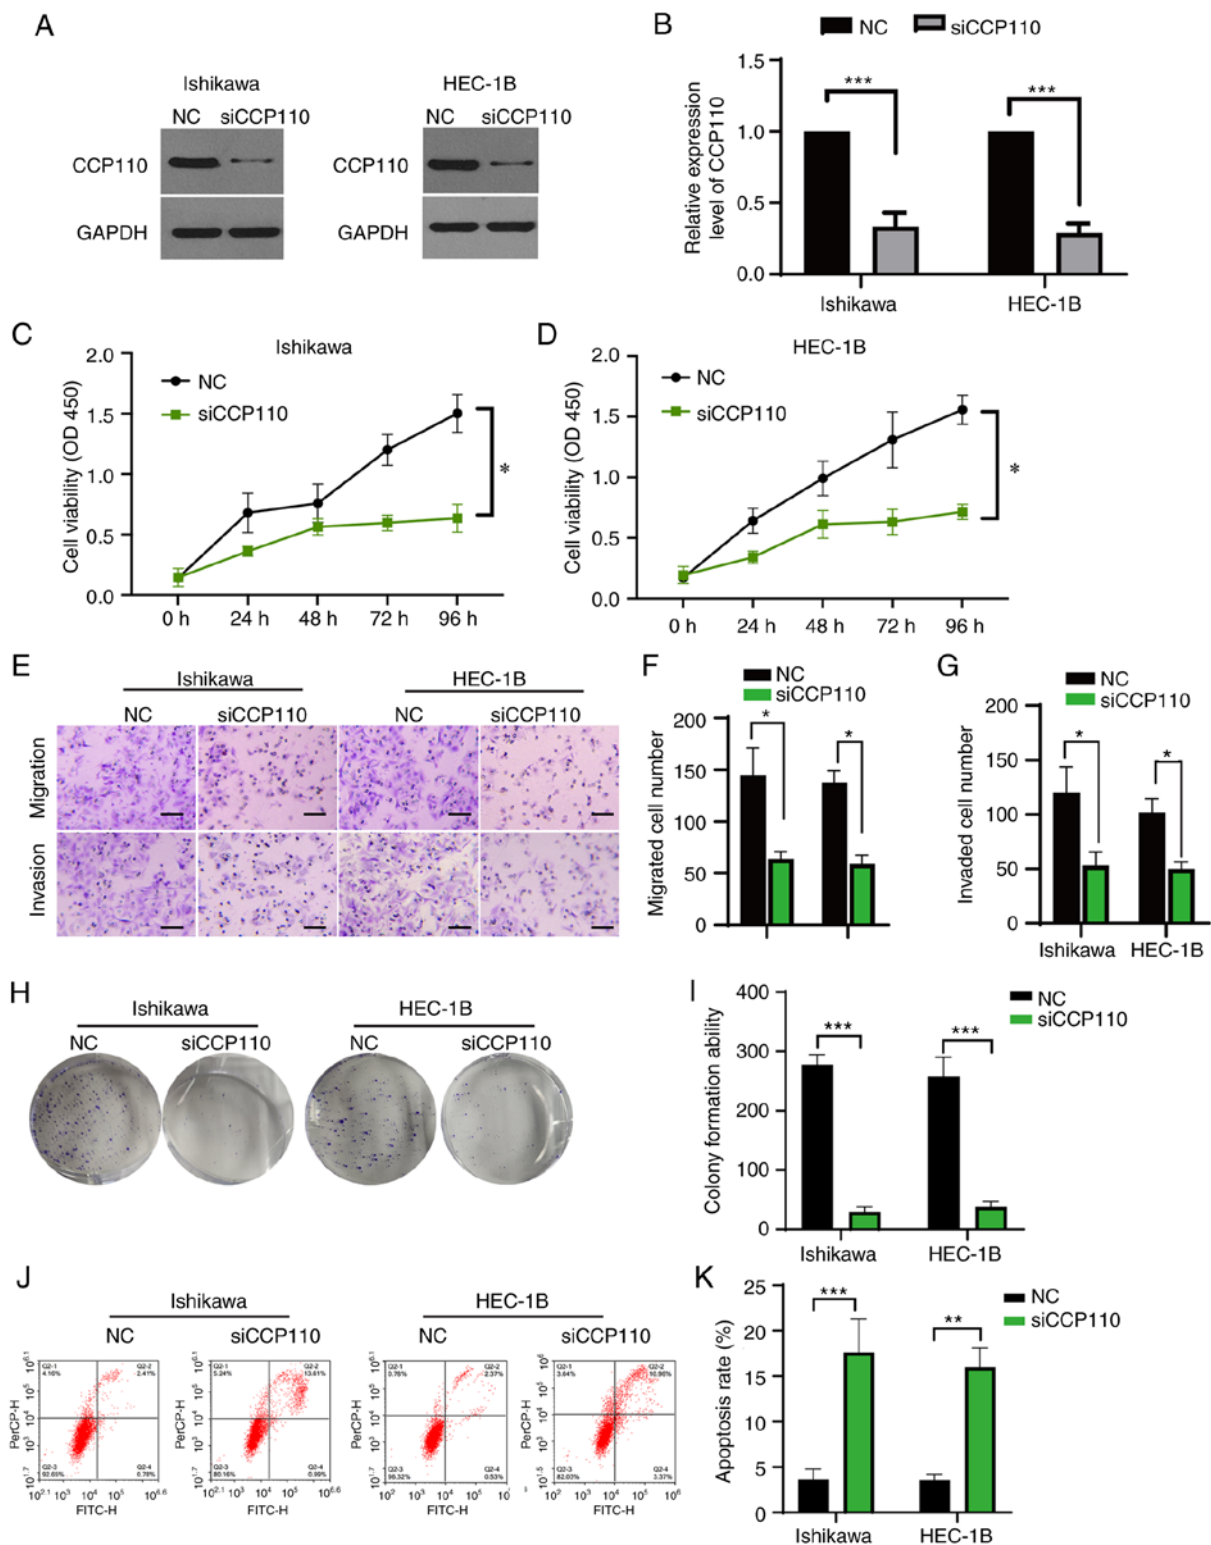

Figure 2. Inhibition of CCP110 suppresses the development of EC cells. Ishikawa and HEC-1B EC cell lines were transfected with a NC siRNA or a CCP110-specific siRNA (siCCP110) and lysed 24 h later. (A) Expression levels of CCP110 and GAPDH were detected using western blotting and then (B) quantified. Growth rates of the transfected (C) Ishikawa and (D) HEC-1B cells were determined using a Cell Counting Kit-8 assay. (E) A Transwell assay to detect migration and invasion of the transfected cells (scale bar, 20 μm); the results of the Transwell assay (F) migration and (G) invasion were then quantified. MiR129-2-3p attenuates EC cell growth and migration by targeting CCP110. Next, the present study attempted to elucidate the molecular mechanism underlying the role of

CCP110 in EC. A bioinformatics analysis identified two potential binding sites for miR-129-2-3p in the 3' UTR region of *CCP110* (Fig. 3A). Consequently, CCP110 luciferase
Figure 3. MiR-129-2-3p targets CCP110 and regulates EC cell development. (A) Bioinformatic prediction of miR-129-2-3p binding sites in the *CCP110* 3' UTR. A Cell Counting Kit-8 assay to measure the growth rates of (F) Ishiwaka and (G) HEC-1B EC cell lines transfected with a NC mimic, miR-129-2-3p mimic, miR-129-2-3p mimic + empty vector or miR-129-2-3p mimic + CCP110-expressing vector. (H) Colony formation and (I) quantification; (J) Transwell (scale bar, 20 µm) (K) migration and (L) invasion assays using the cells described in panels F and G. *P<0.05, **P<0.01. miR, microRNA; CCP110, centromere coiled-coil protein 110; EC, endometrial carcinoma/cancer; UTR, untranslated region; WT, wild-type; MUT, mutant; NC, negative control; OD, optical density.

reporter plasmids containing WT or MUT versions of the miR-129-2-3p binding sequences were constructed (Fig. 3A).

The WT and MUT reporter constructs were co-transfected into Ishikawa and HEC-1B cells with a miR-129-2-3p mimic
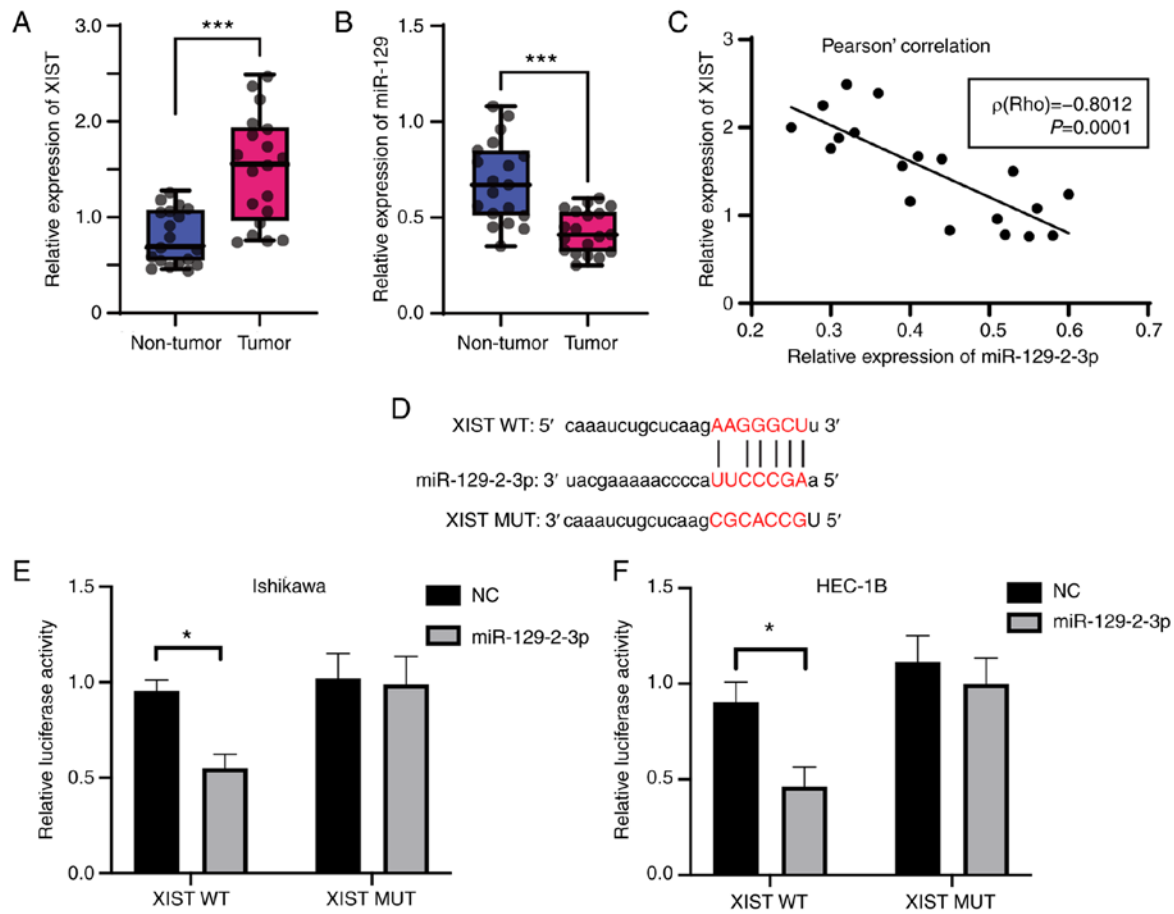

Figure 4. LncRNA XIST targets miR-129-2-3p. EC tissues and paracancerous tissues from 19 patients were subjected to reverse transcription-quantitative PCR assays to detect the expression levels of (A) XIST and (B) miR-129-2-3p. (C) Linear correlation analysis of the expression levels of XIST and miR-129-2-3p in EC tissues. (D) Bioinformatical analysis of binding sites for miR-129-2-3p and XIST. Luciferase reporter gene analysis of (E) Ishiwaka and (F) HEC-1B EC cell lines transfected with a WT or MUT XIST reporter and a miR-129-2-3p mimic or NC mimic. *P<0.05, ***P<0.001. or NC mimic. The expression levels of miR-129-2-3p were first verified using RT-qPCR (Fig. S2). In both cell lines, compared with the NC mimic group, the relative luciferase activity of the WT CCP110 reporter plasmid was significantly reduced after co-transfection with the miR-129-2-3p mimic compared with the mimic NC, whereas co-transfection with the miR-129-2-3p mimic had no significant effect on the relative luciferase activity of the MUT reporter (Fig. 3B and C).

To examine the regulatory relationship between miR-129-2-3p and CCP110 further, both EC cell lines were transfected with a NC mimic, miR-129-2-3p mimic, NC inhibitor or a miR-129-2-3p inhibitor. Cells were collected after 24 h, lysed and subjected to western blotting to detect CCP110 expression. The miR-129-2-3p mimic inhibited the expression of CCP110 significantly in both Ishikawa and HEC-1B cells compared with the mimic NC, whereas the miR-129-2-3p inhibitor significantly increased the protein expression compared with the inhibitor NC (Fig. 3D and E).

Next, the impact of miR-129-2-3p-regulated CCP110 expression was examined in endometrial cell function. The expression levels of CCP110 by overexpression of pcDNA3.1-CCP110 encoding plasmids in two cell lines were verified and shown in Fig. S3A and B. A CCK-8 assay revealed that transfection with the miR-129-2-3p mimic suppressed the growth of both EC cell lines significantly compared with the mimic NC, and co-overexpression of CCP110 rescued this inhibitory effect (Fig. 3F and G). Moreover, the colony formation abilities (Fig. 3H and I) and Transwell migratory activities (Figs. 3J-L and S3C) of both cell lines were suppressed by transfection with the miR-129-2-3p mimic, and these effects were neutralized by co-overexpression of CCP110. Taken together, these data suggested that miR-129-2-3p regulated the development of EC by modulating CCP110 expression.

LncRNA XIST targets miR-129-2-3p in EC cells. Given its role in controlling CCP110 expression and the development of EC, the present study examined the mechanism by which miR-129-2-3p was regulated. lncRNAs can act as miRNA sponges, reducing their regulatory effect on mRNAs (47). XIST, the first lncRNA identified in mammals (48), was investigated because, to the best of our knowledge, there are few reports of its involvement in EC and the detailed mechanism remains to be determined. Thus, RT-qPCR was used to examine the expression levels of XIST and miR-129-2-3p in cancerous and paracancerous tissues collected from 19 patients with EC. Compared with those in paracancerous tissues, the expression levels of XIST (Fig. 4A) and miR-129-2-3p (Fig. 4B) were, significantly upregulated and downregulated, respectively, in
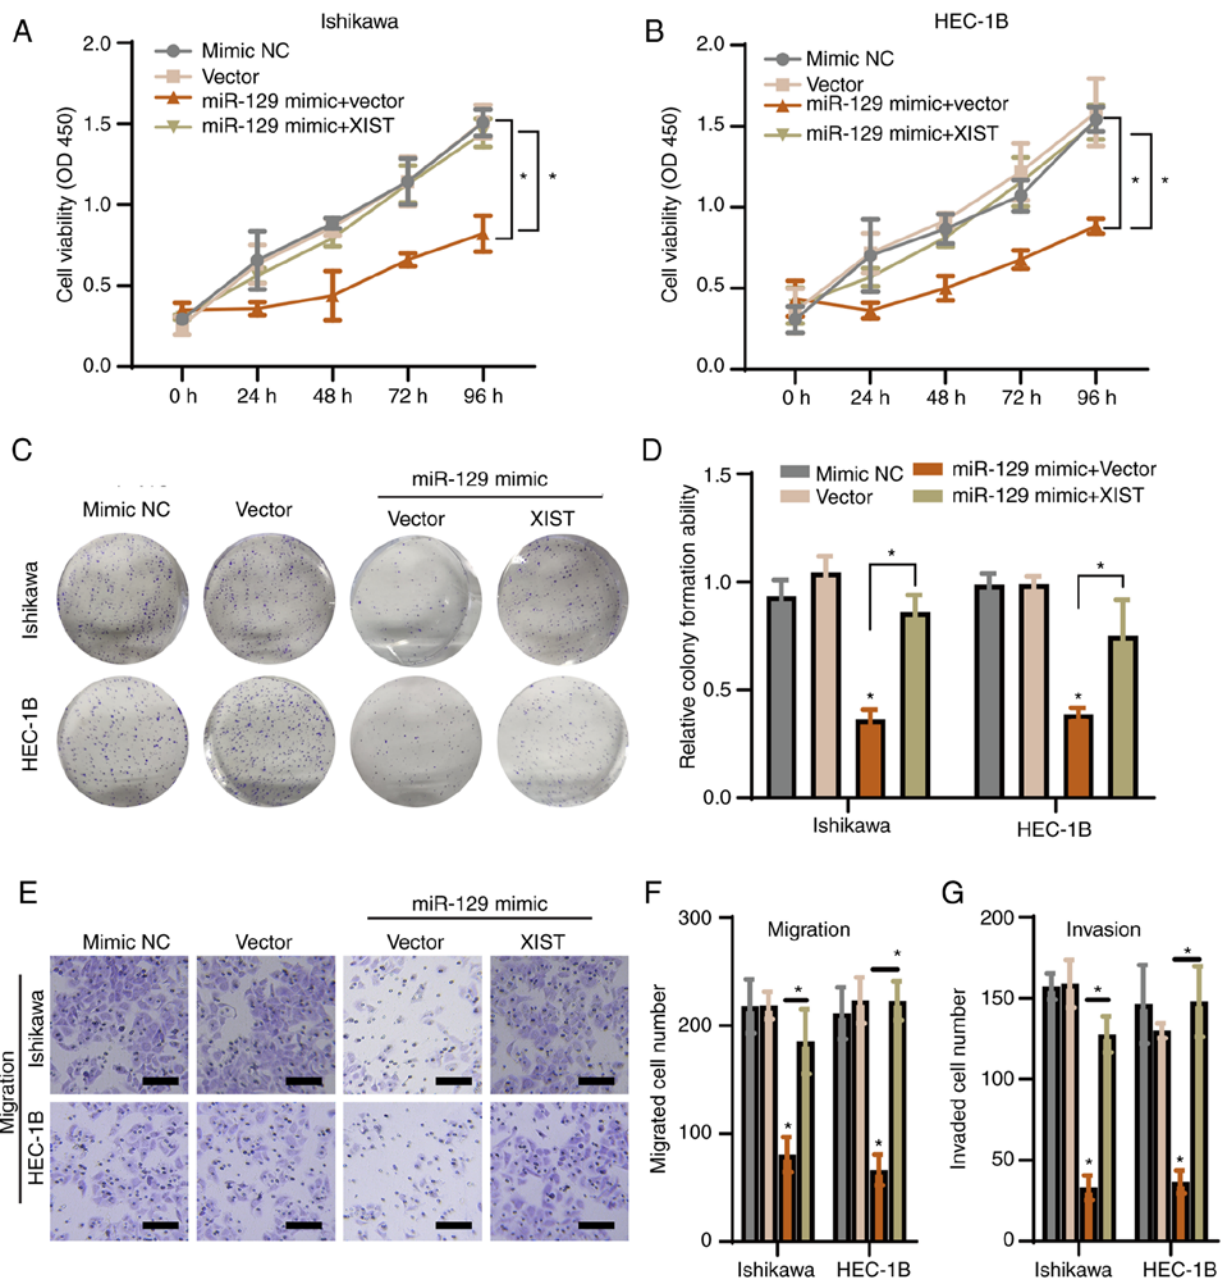

Figure 5. Development of EC cells is regulated by the XIST/miR-129-2-3p axis. CCK-8 assay of (A) Ishikawa and (B) HEC-1B EC cell lines transfected with vector only, a NC mimic, a miR-129-2-3p mimic + vector or a miR-129-2-3p mimic + XIST vector. (C) Colony formation and (D) quantification; (E) Transwell assays and quantification of (F) migration and (G) invasion of the cells (scale bar, 20 μm) described in panels A and B. *P<0.05. cancer tissues. In addition, the expression levels of XIST and miR-129-2-3p were negatively correlated [Rho value (r)=0.608; Fig. 4C]. A bioinformatics prediction revealed the existence of interaction sites between XIST and miR-129-2-3p (Fig. 4D), suggesting a potential targeting relationship between the two.

Next, XIST luciferase reporter plasmids containing a WT or MUT version of the predicted miR-129-2-3p binding site were created and co-transfected into Ishikawa and HEC-1B cells with a miR-129-2-3p mimic or NC mimic. Co-transfection of the miR-129-2-3p mimic significantly reduced the relative luciferase activity of the XIST WT reporter compared with the NC group, but had no such effect on that of the XIST MUT reporter (Fig. 4E and F). Overall, these data indicated the lncRNA XIST targeted miR-129-2-3p in EC cells.

XIST/miR-129-2-3p axis regulates the development of EC cells. To examine the role of the lncRNA XIST/miR-129-2-3p axis in EC further, Ishikawa and HEC-1B cells were transfected with vector only, a NC mimic, a miR-129-2-3p mimic + vector or a miR-129-2-3p mimic + XIST vector. The expression levels of XIST by overexpression of pcDNA3.1-XIST encoding plasmids in two cell lines were verified using RT-qPCR and shown in Fig. S4A. A CCK-8 assay showed that the miR-129-2-3p mimic inhibited EC cell proliferation (compared to the vector group), while overexpression of XIST antagonized this effect in both cell lines (Fig. 5A and B). Furthermore, in both cell lines, overexpression of XIST significantly antagonized the miR-129-2-3p mimic-induced inhibition of cell colony formation (Fig. 5C and D) and migration and invasion ability
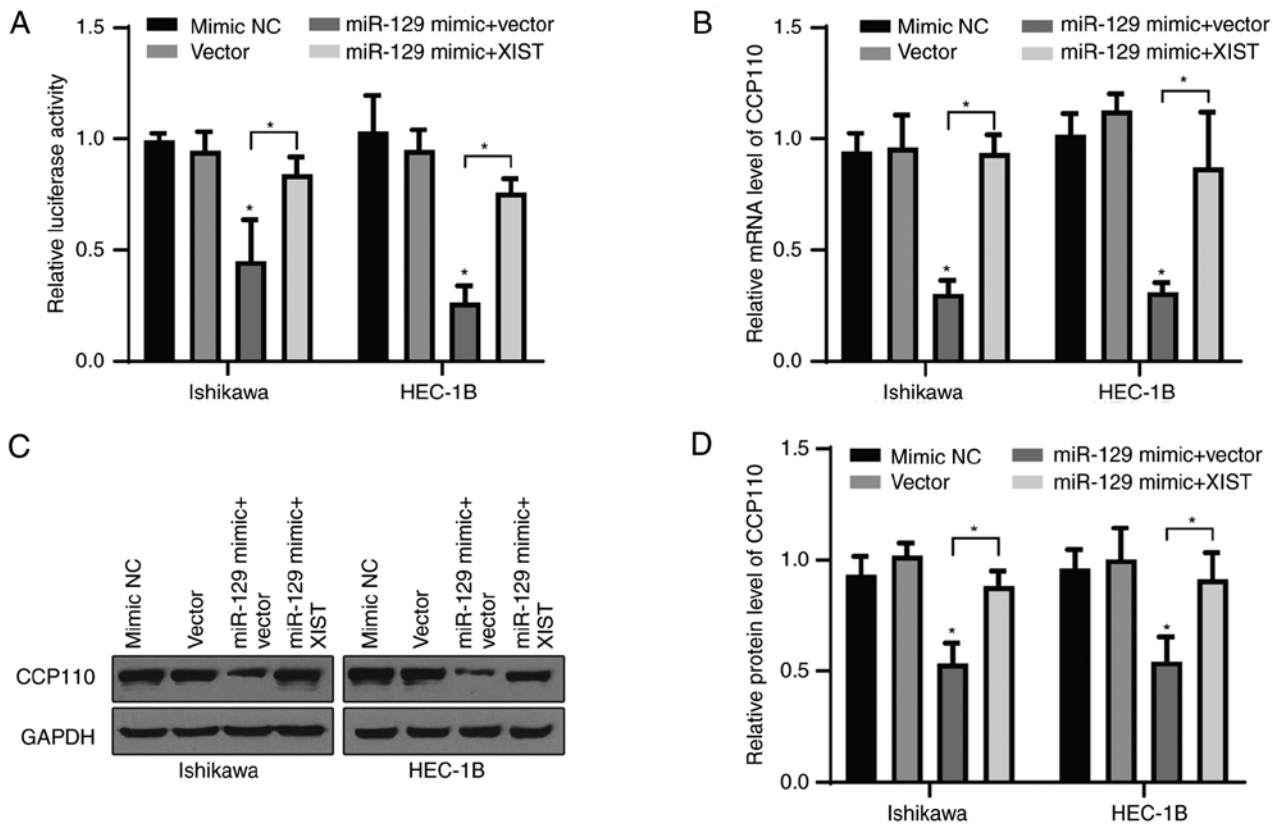

Figure 6. Expression of CCP110 is directly modulated by the XIST/miR-129-2-3p axis. (A) Luciferase reporter gene analysis of Ishikawa and HEC-1B EC cell lines co-transfected with a CCP110 reporter plasmid and either vector only, a NC mimic, a miR-129-2-3p mimic + vector or a miR-129-2-3p mimic + XIST vector. The effects of overexpression of miR-129-2-3p and XIST on CCP110 gene and protein levels in EC cell lines, as determined using (B) reverse transcription-quantitative PCR (B) and (C) western blotting (D) quantification analyses. $^{*}P<0.05$. CCP110, centromere coiled-coil protein 110; EC, endometrial carcinoma/cancer; XIST, X-inactive-specific transcript; miR, microRNA; NC, negative control.

(Figs. 5E-G and S4). These data suggested that the lncRNA XIST functions via miR-129-2-3p to regulate the proliferation, migration and invasion of EC cells.

XIST/miR-129-2-3p axis modulates the expression of CCP110. Given its targeting relationship with miR-129-2-3p, the present study examined whether XIST could regulate the expression of CCP110 through miR-129-2-3p. Ishikawa and HEC-1B cells were co-transfected with a WT CCP110 reporter and either vector only, a NC mimic, a miR-129-2-3p mimic + vector or a miR-129-2-3p mimic + XIST vector, and then subjected to a luciferase reporter assay. Compared with the control group, the miR-129-2-3p mimic + vector group displayed a significantly decreased relative luciferase activity in both cell lines, while overexpression of XIST abolished the inhibitory effect of miR-129-2-3p (Fig. 6A). Furthermore, the miR-129-2-3p mimic suppressed the mRNA (Fig. 6B) and protein (Fig. 6C and D) levels of CCP110 significantly in both cell lines, and these effects were alleviated by overexpression of XIST. Overall, these data suggested that the XIST/miR-129-2-3p axis regulated the development of EC cells by modulating CCP110 expression.

Discussion

EC endangers the physical and mental health of women and occurs most frequently in menopausal women (49). At present,

there are no specific markers of EC in laboratory tests, resulting in delayed detection of the disease (50). CCP110 is involved in the interaction of several protein complexes that regulate centrosome replication and segregation, chromosome segregation and cilia formation, and it structurally regulates microtubule growth and centriole length (51,52). High expression levels of CCP110 induce centrosome expansion, which subsequently delays centrosome segregation and promotes centrosome aggregation (14). Thus, CCP110 is closely associated with tumor development and its inhibition suppresses the development of several types of cancer (53,54). However, the role of CCP110 in EC has previously been unclear.

The current study investigated the role of CCP110 in regulating the proliferation, migration, invasion and colony formation ability of EC cells, and identified miR-129-2-3p and the lncRNA XIST as upstream signals. CCP110 expression was upregulated in EC tissues and was closely related to the prognosis of patients. Genetic knockdown of CCP110 increased apoptosis and suppressed the proliferation, migration, invasion and colony formation ability of EC cells significantly. A bioinformatics analysis and luciferase reporter assay identified CCP110 as a direct target of miR-129-2-3p. Overexpression of miR-129-2-3p suppressed the proliferation, migration, invasion and colony formation ability of EC cells, and these effects were counteracted by overexpression of CCP110. The expression level of the lncRNA XIST was upregulated in EC tissues, while that of miR-129-2-3p was downregulated, and the expression

levels of these two species were negatively correlated. Overall, the present study identified a novel regulatory pathway in which XIST acted as a sponge to inhibit miR-129-2-3p, leading to upregulation of CCP110 and a subsequent increase in the proliferation, migration, invasion and colony formation ability of EC cells. These findings identified CCP110, miR-129-2-3p and XIST as potential targets for the clinical treatment of EC.

As a member of the miR-129 family, miR-129-2-3p occupies an important position in cancer development and other diseases (55). For example, miR-129-3p expression is decreased in rheumatoid arthritis, and its overexpression suppresses expression of the inflammatory cytokine IL-17 to abolish rheumatoid arthritis (56). In one study, during the pathogenesis of osteoarthritis, overexpression of miR-129-3p has been shown to significantly improve articular chondrocyte viability and reduce apoptosis (57). In the cardiovascular system, overexpression of miR-129-3p ameliorates cardiomyocyte inflammation and apoptosis (58). In the nervous system, downregulation of miR-129-3p increases calcium overload, reactive oxygen species production, MMP-2 expression and apoptosis, leading to changes in neuronal function (59). In addition, miR-129-2-3p plays a notable role in cancer development, with altered expression in various tumors. For example, miR-129-3p expression is downregulated in prostate cancer, and its overexpression inhibits the proliferation and invasion of prostate cancer cells, promotes cell regulation, increases expression of the pro-apoptotic protein Bax and decreases expression of the anti-apoptotic protein Bcl-2 (60). Furthermore, overexpression of miR-129-3p reduces CCP110 levels in prostate cancer cells and prevents the production of excess centrosomes (18), which is line with the current findings in EC cells. MiR-129-3p expression is also reduced in gastric cancer tissues and its overexpression inhibits the proliferation, migration and invasion of gastric cancer cells (54). The antitumor effects of miR-129-3p in gastric cancer cells include repression of SUMO-activating enzyme subunit 1 expression by direct targeting of the 3'UTR and suppression of the SUMOylation of X-ray repair cross complementing 4, which disrupts the nuclear localization of the protein (61). Overexpression of miR-129-3p also inhibits the metastasis and invasion of hepatocellular carcinoma cells by inducing inactivation of the PI3K/Akt and p38-MAPK signaling pathways (62-64). Low expression of miR-129-2-3p is significantly correlated with the malignant clinical features of patients with intrahepatic cholangiocarcinoma (65).

The lncRNA XIST plays an important role in the progression of cancer, acting as a sponge to target miRNAs and affect the biological function of tumors (66). In non-small cell lung cancer, overexpression of XIST promotes the proliferation, invasion and metastasis of cancer cells, acting as an oncogene regulating a variety of miRNAs and signaling pathways, such as miR-186-5p, miR-374a, miR-744/RING and CXCR4 (67-70). In esophageal cancer, XIST activates the miR-494/CDK6/JAK2/STAT3 signaling pathway to induce carcinogenesis (71), and knockdown of XIST inhibits the malignant behavior of esophageal cancer cells by antagonizing miR-129-5p/CCND1 signaling (72). XIST also has an oncogenic role in lung cancer and affects tumor progression by regulating the miR-140/iASPP axis and TCF-4 expression (73). XIST expression also predicts poor prognosis and promotes malignant phenotypes in osteosarcoma (74). Furthermore, XIST regulates osteosarcoma cell proliferation, migration, invasion, epithelial-mesenchymal transition and apoptosis, participating in gene regulation through multiple mechanisms (75-79). In the present study, XIST was upregulated in EC tissues and its expression level was negatively correlated with that of miR-129-2-3p. The present study revealed that the inhibitory effect of miR-129-2-3p on the proliferation, metastasis and invasion of EC cells was abolished by overexpression of XIST, which suggested a direct relationship between the two species. Thus, as in other types of cancer, XIST appeared to act as an oncogene in EC by modulating the activity of miR-129-2-3p, leading to upregulation of CCP110. This proposed regulatory mechanism should be explored further in nude mice or other animal models.

To summarize, the present study reported the upregulation of CCP110 in EC tissues and characterized its regulation by a novel signal pathway involving miR-129-2-3p and the lncRNA XIST. The current study identified a novel role for the XIST/miR-129-2-3p/CCP110 axis in regulating endometrial cell growth, colony formation, migration and invasion, which could provide new insights into the clinical management of EC.

Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions

SC and YS designed the experiments, drafted the manuscript, performed the experiments and analyzed and interpreted the data. YL helped with data collection and analysis. YS coordinated the research and participated in the experimental design. XW conceived the idea and conducted the project. All authors were involved in critically revising the manuscript, and have read and approved the final manuscript. SC and YS confirm the authenticity of all the raw data.

Ethics approval and consent to participate

Written consent was signed by the patients, and the study was approved by the ethics committee of Jinan University (approval no. 20210826-25; Guangzhou, China).

Patient consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
