Abstract. There is strong evidence to suggest that angiotensin-converting enzyme inhibitors (ACEIs) protect against local myocardial ischemia/reperfusion (I/R) injury. This study was designed to explore whether ACEIs exert cardioprotective effects in a swine model of cardiac arrest (CA) and resuscitation. Male pigs were randomly assigned to three groups: sham-operated group, saline treatment group and enalapril treatment group. Thirty minutes after drug infusion, the animals in the saline and enalapril groups were subjected to ventricular fibrillation (8 min) followed by cardiopulmonary resuscitation (up to 30 min). Cardiac function was monitored, and myocardial tissue and blood were collected for analysis. Enalapril pre-treatment did not improve cardiac function or the 6-h survival rate after CA and resuscitation; however, this intervention ameliorated myocardial ultrastructural damage, reduced the level of plasma cardiac troponin I and decreased myocardial apoptosis. Plasma angiotensin (Ang) II and Ang-(1-7) levels were enhanced in the model of CA and resuscitation. Enalapril reduced the plasma Ang II level at 4 and 6 h after the return of spontaneous circulation whereas enalapril did not affect the plasma Ang-(1-7) level. Enalapril pre-treatment decreased the myocardial mRNA and protein expression of angiotensin-converting enzyme (ACE). Enalapril treatment also reduced the myocardial ACE/ACE2 ratio, both at the mRNA and the protein level. Enalapril pre-treatment did not affect the upregulation of ACE2, Ang II type 1 receptor (AT1R) and MAS after CA and resuscitation. Taken together, these findings suggest that enalapril

protects against ischemic injury through the attenuation of the ACE/Ang II/AT1R axis after CA and resuscitation in pigs. These results suggest the potential therapeutic value of ACEIs in patients with CA.

Introduction

Sudden cardiac arrest (CA) is a major burden on health care in the US, with estimates ranging from 200,000 to 500,000 patients who experience out-of-hospital CA each year (1). The median rate of survival in adults following hospital discharge is approximately 6.7% in the US (2). It has been widely accepted that cardiopulmonary resuscitation (CPR) is an important first aid technique for CA. A 9-year retrospective cohort study of 5,958 patients receiving emergency medical service (EMS)-initiated resuscitation demonstrated that 16.8% survived at hospital discharge. Of those individuals discharged, 5-year survival was better in those who had received percutaneous coronary intervention (3). Notably, a recent randomized controlled trial has demonstrated that mild therapeutic hypothermia for 12-24 h improves neurologic recovery and survival after CA (4). However, even after successful CPR and therapeutic hypothermia treatment, myocardial tissue may still suffer from severe ischemia/reperfusion (I/R) injury. In many patients who initially achieve return of spontaneous circulation (ROSC) after CA, subsequent morbidity and mortality is caused by cardiac ischemia that accompanies prolonged cardiac dysfunction (5). This disease is known as post-cardiac arrest syndrome (PCAS) (5), which is a serious threat to patient health. A better understanding of the cellular and molecular mechanisms responsible for myocardial ischemia may assist in the development of more efficient treatment strategies for PCAS.

The renin-angiotensin-aldosterone system (RAAS) is an endogenous hormonal cascade that functions in the homeostatic control of arterial pressure, extracellular volume and tissue perfusion (6). Currently, blockade of the RAAS with angiotensin-converting enzyme inhibitors (ACEIs) or angiotensin II type 1 receptor (AT1R) blockers (ARBs) has been widely used as a treatment strategy in the management of patients with hypertension, acute myocardial infarction, chronic systolic heart failure, stroke and diabetic renal disease (6). However, these drugs are also associated with adverse reactions, such as hypotension (6). Following

Key words: angiotensin-converting enzyme inhibitor, cardiac arrest, resuscitation, pig, ischemia/reperfusion

myocardial I/R injury, the cardioprotective effects of ACEIs have been well established (7). ACEIs are capable of acutely limiting myocardial injury and necrosis in models of permanent coronary artery occlusion. The mechanisms responsible for this cardioprotection include reductions in myocardial oxygen supply/demand, inhibition of bradykinin metabolism, increased prostaglandin synthesis and attenuated inflammatory responses (8). However, there is limited data regarding the application of ACEIs or ARBs in a model of CA and resuscitation, which features complex pathophysiological changes such as brain ischemia and renal ischemia (9,10). Furthermore, there is concern that blockade of the RAAS reduces perfusion pressure, which may attenuate the beneficial effects of resuscitation.

Thus, we performed this study in order to examine the effects of enalapril pre-treatment on myocardial injury in a swine model of CA and resuscitation. We examined the effects of enalapril infusion on myocardial ultrastructure, hemodynamics and RAAS system activation, including the plasma levels of angiotensin (Ang) II and Ang-(1-7). Finally, the effects of enalapril pre-treatment on the mRNA and protein levels of angiotensin-converting enzyme (ACE), AT1R, ACE2 and MAS were evaluated in swine myocardial tissue.

Materials and methods

Animals. Inbred, male, Landrace miniature piglets aged 11-13 months, with an average weight of 30 ± 2 kg, were used as previously described (11). All procedures were performed in accordance with the Animal Care Guidelines of the Institutional Animal Care and Use Committee of Capital Medical University (Beijing, China) as well as the Utstein-style guidelines (12). The experimental protocol was also approved by the Committee on the Ethics of Animal Experiments of Capital Medical University. All animals were housed in a dedicated, pathogen-free environment in the Capital Medical University animal facility. Animals were fed standard chow and had free access to water.

Groups, anesthesia and ventilation. The pigs were randomly assigned to three groups: the sham-operated group (sham group, $n=8$), the experimental CA-resuscitation + saline (0.9% NaCl) group (saline group, $n=12$) and the experimental CA-resuscitation + enalapril group (enalapril group, $n=12$). On the experimental day, anesthesia was induced by an intramuscular injection of midazolam (0.5 mg/kg) followed by an injection of propofol (1.0 mg/kg via an ear vein). The animals were anesthetized with an intravenous infusion of sodium pentobarbital (8 mg/kg/h) to maintain favorable surgical anesthesia. The chest and back were thoroughly shaven to allow for direct contact of the paddles used for defibrillation during CPR immediately following the induction of anaesthesia.

An endotracheal tube (6.5-mm internal diameter) was used as an ordinary endotracheal tube. The tube was connected to a Servo Ventilator (Servo 900C; Siemens, Munich, Germany) with an FiO_2 of 0.21. All the animals were intubated and mechanically ventilated with room air using a tidal volume of 12 ml/kg and a respiratory frequency of 12 breaths/min. Respiratory frequency was adjusted to maintain end-tidal pCO_2 between 35 and 40 mmHg, which was continuously

monitored using an infrared CO_2 analyzer ($\text{CO}_2\text{SMO Plus}$ monitor; Respirometric Inc., Murrysville, PA, USA).

Preparation and monitoring. Acetated Ringer's solution (30 ml/kg) was infused via an ear vein to compensate for fluid loss during the first hour of preparation. During the procedure, 2.5% glucose-electrolyte solution (8 ml/kg/h) was continuously infused. A Swan-Ganz catheter (7 Fr; Edwards Life Sciences, Irvine, CA, USA) was inserted into the pulmonary artery via the right external femoral vein for cardiac output (CO) measurement (13). Electrocardiogram and hemodynamic parameters were monitored using the M1165 monitoring system (Hewlett-Packard, Palo Alto, CA, USA). Self-adhesive defibrillation electrodes were positioned on the chest wall. Coronary perfusion pressure (CPP) was calculated as the difference, measured at the end of each minute of precordial compression, between decompression diastolic aortic and time-coincident right-atrial pressure.

Experimental procedure. Experimental ventricular fibrillation (VF) in pigs was induced in the saline and enalapril groups, but not in the sham group, as described previously (11). Pure enalapril (E6888) was purchased from Sigma-Aldrich (St. Louis, MO, USA). Following the surgical preparations described above, baseline measurements and blood samples were obtained. Then, the animals were intravenously infused with enalapril solution (0.2 mg/kg) or an equal volume of saline 30 min prior to VF induction. This dose was selected based on data from a previous study (14).

Successful VF was induced using a method described in previous study from our laboratory (15). A temporary pace-maker conductor was inserted into the right ventricle through the right sheathing canal and connected to an electrical stimulator (GY-600A; Kaifeng Huanan Equipment Co., Ltd., Kaifeng, China). The electrical stimulator was programmed in the SIS2 mode (300/200 msec, 40 V, 8:1 proportion and 10 msec step length) to provide a continuous electrical stimulus until the occurrence of VF. Ventricular fibrillation was defined as an electrocardiogram showing waveforms corresponding to VF and a rapid decline in mean arterial pressure (MAP) toward zero (16).

Mechanical ventilation was stopped after successful VF induction. At 8 min post VF induction, monophasic electrical shock was attempted, beginning at 3 J/kg. If the initial defibrillation shock failed, energy was increased by 1 J/kg increments for subsequent defibrillation shocks. If the first defibrillation was unsuccessful, CPR was performed for 2 min and the second defibrillation was induced. Manual CPR was carried out at a frequency of 100 compressions/min with mechanical ventilation at an FiO_2 of 100% and a compression-to-ventilation ratio of 30:2. The swine chest was compressed to approximately one third of the anteroposterior diameter. Notably, the same CPR technician performed CPR throughout the entire study. The quality of chest compressions was controlled by a HeartStart MRx Monitor/Defibrillator with Q-CPR (Philips Medical Systems, Best, The Netherlands). The compression-to-ventilation ratio was 30:2 (17). If spontaneous circulation was not achieved after the second defibrillation attempt, CPR was continued for an additional 2 min, and defibrillation was attempted a third time. In this manner, CPR was continued for up to 30 min. Only the

principal investigator, who did not take part in any resuscitation efforts, knew the treatment group assignment of each animal.

ROSC was defined as 10 consecutive min of systolic blood pressure at 50 mmHg. At 30 min after CPR, those animals remaining in VF, pulseless electrical activity or asystole were considered resuscitation failures (18). After successful resuscitation, the animals were mechanically ventilated with 100% oxygen. During the next 6 h, the animals were maintained in a surgical plane of anesthesia with an intravenous infusion of sodium pentobarbital (8 mg/kg/h). Heart rate (HR), CO, CPP and MAP were monitored in these animals hourly. Blood samples were obtained and blood plasma was prepared at 0, 30 min, 1, 2, 4 and 6 h post-ROSC from the sham, saline- and enalapril-treated groups. During this period, two pigs in the saline-treated group and one pig in the enalapril-treated group died due to sudden cardiac arrest. At the end of the experiments, the animals were euthanized with intravenous potassium chloride (15%, 10 ml). The cardiac tissue was isolated, immediately frozen in liquid nitrogen, and stored at -80°C .

Hemodynamic measurements. Hemodynamic parameters were measured at baseline and 0.5, 1, 2, 4 and 6 h after ROSC. Measured parameters included HR, CO, CPP and MAP. MAP was monitored via a right femoral arterial catheter.

Enzyme-linked immunosorbent assay (ELISA). Plasma levels of Ang II and Ang-(1-7) were measured. Plasma Ang II levels were determined using a commercial ELISA kit purchased from R&D Systems (Minneapolis, MN, USA) and plasma Ang-(1-7) plasma levels were determined using a commercial ELISA kit purchased from BlueGene Biotech Co., Ltd. (Shanghai, China). The ELISA samples consisted of 50 μl blood plasma and 50 μl deionized water in a 96-well plate, according to the manufacturer's instructions. Optical density (OD) values (450 nm) were determined using a microplate reader (Tefcan M200; Tecan, Crailsheim, Germany) as previously described (19).

Measurement of plasma cardiac enzyme levels and a terminal deoxynucleotidyl transferase-mediated dUTP nick-end labeling (TUNEL) assay. According to the manufacturer's instructions, the plasma cardiac troponin I (cTNI) level was determined using a high-sensitive assay (Abbott Diagnostics, Lake Forest, IL, USA), and TUNEL assay was performed using a commercial kit (*In Situ* Cell Death Detection kit; Roche, Mannheim, Germany) (20).

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). RT-qPCR was performed as previously described and according to the manufacturer's protocol (21,22). Total RNA was extracted from the myocardial tissue using TRIzol reagent (Invitrogen, Carlsbad, CA, USA) and then reverse transcribed into cDNA (23). For all experiments, 5 ng cDNA was subjected to RT-qPCR with a Perkin-Elmer ABI Prism 7500 sequence detection system and Power SYBR-Green PCR Master Mix (Applied Biosystems, Life Technologies, Grand Island, NY, USA). The following primers were used: ACE forward, 5'-ATC AAG CGG ATC ATA AAG AAG-3' and reverse, 5'-CAC GCT GTA GGT GGT TTC C-3'; ACE2 forward, 5'-TCT GAA TGA

CAA CAG CCT AG-3' and reverse, 5'-CAC TCC CAT CAC AAC TCC-3'; MAS forward, 5'-TAT TCC TCA TCT TCG CTA T-3' and reverse, 5'-GCC CTG GTC AGA ACA ACT-3'; AT1R forward, 5'-TCA CCT GCA TCA TCA TCT GG-3' and reverse, 5'-AGC TGG TAA GAA TGA TTA GG-3'; and GAPDH forward, 5'-GAC CCA GAA TAC CAA GTG CAG ATG TA-3' and reverse, 5'-CTG TTT CAG GAT TTA AGG TTG GAG ATT-3'. Gene expression was normalized to GAPDH. Data analysis was performed using the $2^{-\Delta\Delta\text{Ct}}$ method (24).

Immunohistochemistry. Immunohistochemical staining was performed as previously described (25). Briefly, the sections were placed in 10 ml glass centrifuge tubes and dewaxed using two changes of xylene (3 ml) for 10 min at room temperature, and then rehydrated in a sequence of 100, 95, 70 and 50% graded ethanol (3 ml). After blocking with 5% BSA for 4 h, the sections were incubated overnight at 4°C with anti-ACE2 (1:100; Abcam, Cambridge, UK), anti-ACE (1:200; Santa Cruz Biotechnology, Dallas, TX, USA), anti-MAS (1:300; Alomone Labs Ltd., Jerusalem, Israel) or anti-AT1R (1:200; Abcam) antibodies. The sections were washed with phosphate-buffered saline (PBS) three times (5 min \times 3) and incubated with biotinylated secondary antibodies (1:200), followed by incubation with an avidin-biotin peroxidase complex (both from ZSGB-Biotechnology, Beijing, China). The sections incubated with normal rabbit serum (1:10) served as negative controls. Peroxidase conjugate localization was determined using 3,3'-diaminobenzidine tetrahydrochloride (DAB; Sigma, Milwaukee, WI, USA) as the chromogen, and the sections were counterstained with hematoxylin (Beijing Solarbio Science & Technology Co., Ltd., Beijing, China). Images were captured using an IX80 microscope (Olympus, Tokyo, Japan) and analyzed using Image Pro Plus v3.0 software (Media Cybernetics, Carlsbad, CA, USA). The positive staining was defined as localization of brown staining.

Western blot analysis. Western blot analysis was performed as previously described (26,27). The heart tissues were swiftly harvested, washed in PBS three times and then homogenized in lysis buffer (Tris-HCl pH 7.5, 20 mmol/l; EDTA, 2 mmol/l; NP-40, 1%; and Triton X-100, 1%) with protease inhibitors [phenylmethylsulfonyl fluoride (PMSF), 2 mmol/l; leupeptin, 50 $\mu\text{g}/\text{ml}$; aprotinin, 25 $\mu\text{g}/\text{ml}$; pepstatin A, 10 $\mu\text{g}/\text{ml}$; and dithiothreitol, 2 mmol/l]. Total protein concentrations were determined using a bicinchoninic acid assay (BCA) assay (Beyotime, Haimen, China). Approximately 30 μg of the homogenate samples were run on a 10% sodium dodecyl sulfate (SDS)-polyacrylamide gel, and the proteins were electrotransferred to nitrocellulose membranes (Bio-Rad Laboratories, Hercules, CA, USA). The membranes were blocked using 5% evaporated milk in PBS and then incubated for 4 h at room temperature with primary antibodies [anti-ACE2 (1:100; ab15348; Abcam), anti-ACE (1:200; sc-20791; Santa Cruz Biotechnology), anti-AT1R (1:100; ab18801; Abcam) and anti-MAS (1:300; AAR-013, Alomone Labs Ltd.) and β -actin (ab8226, Abcam)]. Following incubation, the blots were washed with PBS, and then incubated for 2 h with HRP-conjugated secondary antibodies (1:1,000). HRP signals were detected using an ECL kit (Amersham Biosciences, Little Chalfont, UK). Quantitative analysis of the data was performed by

Table I. Physiological baseline measurements across experimental groups.

Baseline parameters	Sham group (n=8)	Saline group (n=12)	Enalapril group (n=12)
Body weight (kg)	29.13±2.16	30.63±0.92	30.38±0.92
Heart rate (beats/min)	99.00±7.44	101.38±8.30	100.50±10.04
Average arterial pressure (mmHg)	103.12±5.19	101.88±5.22	87.00±5.81
Average pulmonary arterial pressure (mmHg)	23.42±4.32	24.13±5.24	24.34±4.56
Cardiac output (l/min)	2.86±0.22	2.99±0.20	2.99±0.19
CPP (mmHg)	43.5±2.4	41.7± 5.1	42.6± 6.2

Values are the means ± SD. CPP, coronary perfusion pressure.

Table II. Outcome measures after post-resuscitation in sham, saline- and enalapril-treated groups in a swine model of myocardial I/R injury.

Outcome measures	Sham	Saline	Enalapril
Number of shocks	0	3.7±1.5 ^a	2.8±0.9 ^a
Energy of shock (J)	0	292.5±39.8 ^a	276.7±54.6 ^a
Time to ROSC (min)	0	5±1.8 ^a	5.5±1.7 ^a
Number of pigs surviving at 6 h	8 (8/8)	6 (6/12) ^a	9 (9/12) ^a

measuring the intensity of protein band signals using Bio-Rad Image Lab Software (Bio-Rad Laboratories).

Transmission electron microscopy. The heart tissues were carefully isolated and fixed with 2.5% glutaraldehyde in 0.1 M phosphate buffer (pH 7.2-7.4) for 2 h at 4°C. After washing in phosphate buffer, the tissues were post-fixed in 1% osmium tetroxide (Sigma-Aldrich, Shanghai, China) in 0.1 M phosphate buffer for 2 h. The tissues were dehydrated in a graded ethanol series, infiltrated with propylene oxide, embedded in epoxy resin and sliced into ultrathin sections (1 µm). After double-staining with uranyl acetate (Spectrum Chemical Manufacturing Corp., Shanghai, China) and lead citrate (Sigma-Aldrich, Shanghai, China), electron microphotographs were captured using a transmission electron microscope (H-7650; Hitachi, Tokyo, Japan).

Statistical analysis. The results are expressed as the means ± SD. Differences at various time-points within groups were compared with a repeated measures analysis of variance (ANOVA) followed by a Tukey post-hoc test. Continuous variables were adjusted to a normal distribution and equal variances were compared using the Kolmogorov-Smirnov test and homogeneity of variance test. Survival rate comparisons were performed using Chi-square analysis. P<0.05 was considered to indicate a statistically significant difference.

Results

Enalapril does not improve survival rates in a swine model of CA and resuscitation. There were no significant differences in baseline parameters (including body weight, HR, average arterial pressure, average pulmonary arterial pressure and CO) among the sham, saline- and enalapril-treated groups (Table I). Moreover, there were no significant differences in the number of defibrillation shocks, shock energy and outcome between enalapril-treated pigs and saline-treated pigs (P>0.05) (Table II).

Effects of enalapril on hemodynamic indices in a swine model of CA and resuscitation. We measured hemodynamic indices in the sham, saline- and enalapril-treated groups. Resuscitation significantly boosted HR (Fig. 1A) and MAP (Fig. 1C), but reduced CO (Fig. 1B) and CPP (Fig. 1D). Enalapril treatment did not change the HR, CO or CPP (Fig. 1A, B and D). However, enalapril treatment exhibited a marked blood pressure-lowering effect, partly inhibiting the enhancement of MAP at 4 and 6 h post-ROSC (Fig. 1C).

Enalapril ameliorates I/R-induced myocardial injury in a swine model of CA and resuscitation. The effects of enalapril treatment on ultrastructural changes in the myocytes are shown in Fig. 2A. Transmission electron micrographs showed that acute CA and resuscitation resulted in immediate and serious injury to the myocardium of animals in the saline group. The myocytes in the saline group exhibited gigantic vacuoles, disintegration of myofibrils, severe fraying of intercellular organelles and considerable Z-band disruption. Moreover, deranged cristae and significant swelling were observed in mitochondria. By contrast, these injuries were less severe in the myocardium of animals in the enalapril-treated group. In addition, the results of the TUNEL assay showed that myocardial apoptosis in the saline group was markedly induced by CA-resuscitation, an effect that was reversed by enalapril treatment (Fig. 2B). The plasma levels of cTNI, an enzymatic marker for acute myocardial infarction and cardiac cell death, were also markedly enhanced in the saline group at 2 and 6 h after ROSC (Table III). Enalapril treatment significantly inhibited the increase in plasma cTNI levels at 6 h after ROSC (Table III). Taken together, the findings of the present study indicate that enalapril ameliorates

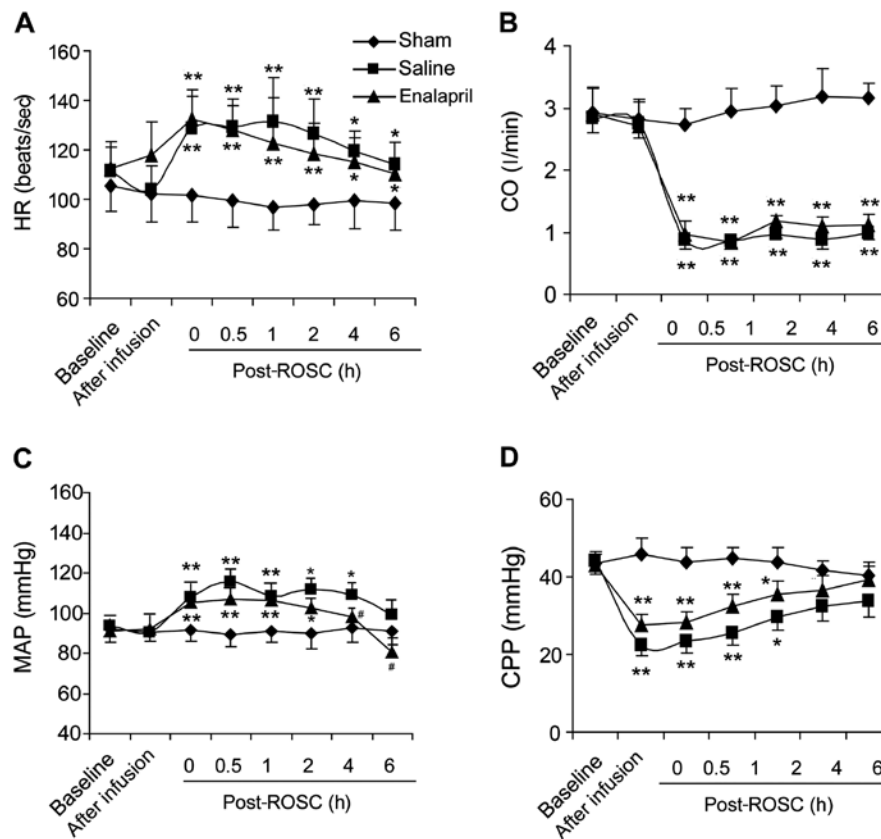

Figure 1. Cardiac functions of pigs post-resuscitation in the sham, saline- and enalapril-treated groups. (A) Heart rate (HR, beats/sec), (B) cardiac output (CO, l/min), (C) mean arterial pressure (MAP, mmHg) and (D) coronary perfusion pressure (CPP, mmHg) were monitored at different time points (baseline, after infusion, 0, 0.5, 1, 2, 4 and 6 h) following restoration of spontaneous circulation (post-ROSC, h). *P<0.05 and **P<0.01 vs. sham group; #P<0.05 vs. saline group. n=8-12/group initially.

I/R-induced myocardial injury in a swine model of CA and resuscitation.

Enalapril decreases plasma Ang II levels but not Ang-(1-7) levels in a swine model of CA and resuscitation. There was

Table III. Plasma cTNI levels in sham, saline- and enalapril-treated groups in a swine model of myocardial I/R injury.

Time after ROSC	Sham	Saline	Enalapril
0 h after ROSC	0.01±0.005	0.01±0.003	0.01±0.007
2 h after ROSC	0.01±0.006	1.99±0.74 ^a	2.12±0.98 ^a
6 h after ROSC	0.01±0.004	4.25±1.20 ^a	3.17±1.05 ^{a,b}

cTNI, cardiac troponin I (ng/ml); I/R, ischemia/reperfusion; ROSC, return of spontaneous circulation. Values are the means ± SD. ^aP<0.01 vs. sham; ^bP<0.05 vs. saline. n=8-12/group initially.

no significant difference in the baseline plasma levels of Ang II (Fig. 3A) and Ang-(1-7) (Fig. 3B) among the three groups. The plasma Ang II levels in the saline group were markedly increased at 2, 4 and 6 h post-ROSC (Fig. 3A). Enalapril treatment significantly reduced the plasma Ang II levels at 4 and 6 h post-ROSC (P<0.05) compared with levels in the saline group (Fig. 3A). The plasma Ang-(1-7) levels in the saline group were also increased at 4 and 6 h post-ROSC (Fig. 3B). Enalapril treatment did not reduce the plasma Ang-(1-7) levels, although there was a trend toward a reduction of Ang-(1-7) levels in the enalapril-treated pigs at 4 and 6 h post-ROSC (Fig. 3B).

Enalapril reduces myocardial ACE expression whereas it has no effect on ACE2 expression in a swine model of CA and resuscitation. The effects of enalapril on myocardial ACE and ACE2 expression were assessed by RT-qPCR, western blot analysis and immunohistochemistry. We found that the mRNA levels of ACE increased by ~3-fold after resuscitation in the saline group compared with that in the sham group (P<0.05) (Fig. 4A). Enalapril treatment inhibited this upregulation of myocardial ACE after resuscitation (P<0.05) (Fig. 4A). The results of western blot analysis revealed that the myocardial ACE protein level in the saline group was ~2.5-fold of that in the sham group, and enalapril suppressed this upregulation

(P<0.01) (Fig. 4B). Immunohistochemical analysis confirmed that ACE protein levels were increased after resuscitation and that this effect was partly inhibited by enalapril treatment (P<0.05) (Fig. 4C). RT-qPCR, western blot analysis and immunohistochemistry revealed that the myocardial mRNA and protein levels of ACE2 were significantly enhanced after resuscitation (P<0.05) (Fig. 5A-C). In contrast to the changes observed in ACE expression, enalapril treatment failed to modulate the myocardial mRNA and protein expression of ACE2 (P>0.05) (Fig. 5A-C). These data indicate that enalapril reduces myocardial ACE expression whereas it has no effect on ACE2 expression after resuscitation in swine.

Enalapril decreases the myocardial ACE/ACE2 mRNA ratio in a swine model of CA and resuscitation. The mRNA and protein ratios of myocardial ACE to ACE2 were determined in each group following resuscitation. The ratios of myocardial ACE/ACE2 mRNA (Fig. 6A) and protein (Fig. 6B) were significantly decreased by enalapril treatment (P<0.05).

Enalapril does not alter AT1R and MAS expression in a swine model of CA and resuscitation. We also measured the mRNA and protein levels of AT1R and MAS in each experimental group using RT-qPCR, western blot analysis and immunohistochemistry. The mRNA level of AT1R was increased ~4-fold after resuscitation in the saline group compared with that in the sham group (P<0.01) (Fig. 7A). Western blot analysis also showed an increase in myocardial AT1R protein levels in the saline group (P<0.01) (Fig. 7B). Immunohistochemical analysis confirmed the upregulation of AT1R protein (Fig. 7C). Enalapril treatment had no effect on the upregulation of AT1R (Fig. 7A-C). Similarly, RT-qPCR, western blot analysis and immunohistochemistry revealed that the mRNA and protein levels of myocardial MAS were significantly enhanced after resuscitation (P<0.01) (Fig. 8). However, enalapril treatment did not modulate the mRNA or protein expression of myocardial MAS (Fig. 8). Taken together, these findings indicate that AT1R and MAS are upregulated after CA and resuscitation, whereas enalapril does not affect their upregulation.

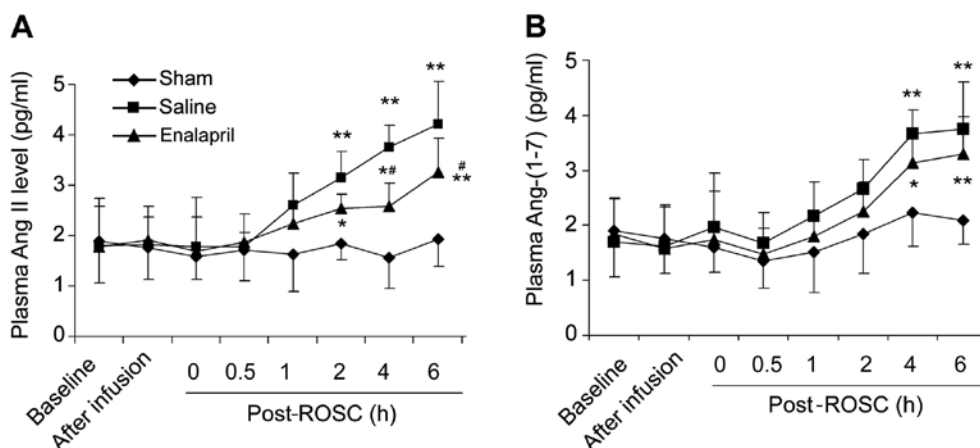

Figure 3. Plasma levels of the renin-angiotensin system components, angiotensin (Ang) II and Ang-(1-7), in a swine model of cardiac arrest (CA) and resuscitation. ELISA determination of (A) Ang II and (B) Ang-(1-7) levels at different time points (baseline, after infusion, 0, 0.5, 1, 2, 4 and 6 h) in sham, saline- and enalapril-treated groups following the return of spontaneous circulation (post-ROSC, h) were determined by ELISA. *P<0.05 and **P<0.01 vs. sham group; #P<0.05 vs. saline group. n=6-9/group.

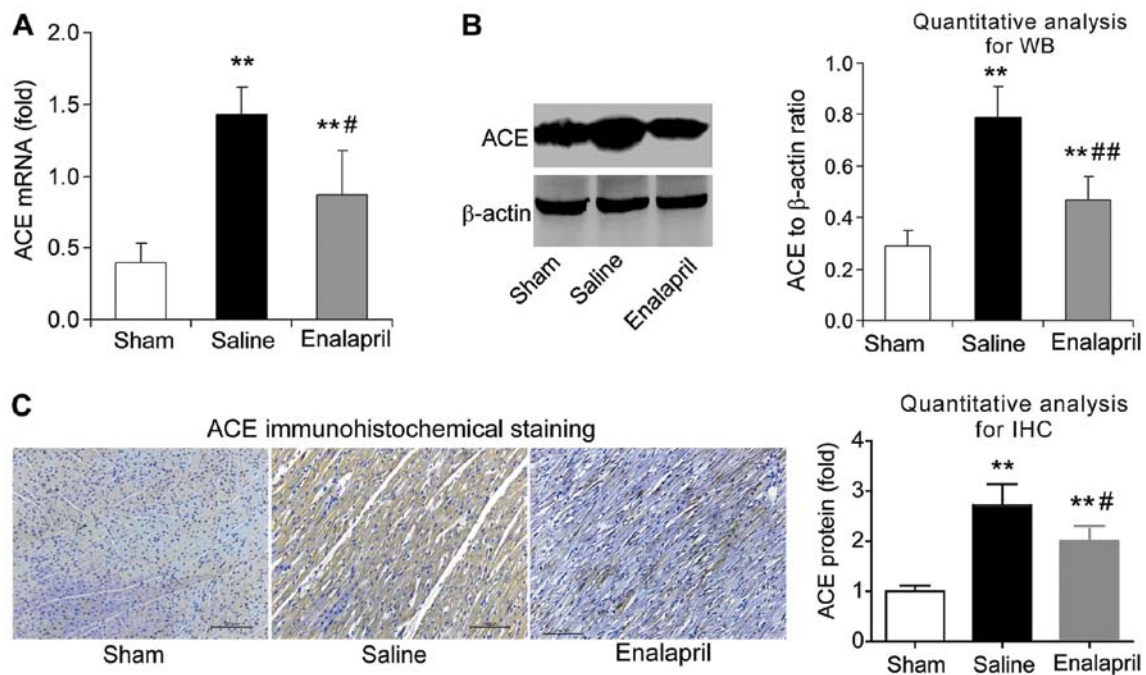

Figure 4. The mRNA and protein levels of angiotensin-converting enzyme (ACE) in myocardial tissue post-resuscitation in a swine model of cardiac arrest (CA)-resuscitation. Effects of enalapril on the mRNA and protein levels of ACE were determined using (A) RT-qPCR, (B) western blot analysis and (C) immunohistochemistry and compared with the sham and the saline-treated groups. * $P < 0.05$ and ** $P < 0.01$ vs. sham group; # $P < 0.05$ and ## $P < 0.01$ vs. saline group. $n = 6-9$ /group. Magnification, $\times 200$ in (C).

Effects of enalapril on the mRNA and protein levels of ACE2 were determined using (A) RT-qPCR, (B) western blot analysis and (C) immunohistochemistry and compared with the sham and saline-treated groups. * $P < 0.05$, ** $P < 0.01$ vs. sham group. NS, no significance. $n = 6-9$ /group. Magnification, $\times 200$ in (C).

Discussion

In the present study, we demonstrated a cardioprotective role for enalapril through modulation of the RAAS in a swine

model of CA and resuscitation. Although enalapril did not improve the survival rate in this model, it greatly ameliorated I/R-induced ultrastructural changes in myocytes, plasma enzyme levels and myocardial apoptosis. Additionally, the

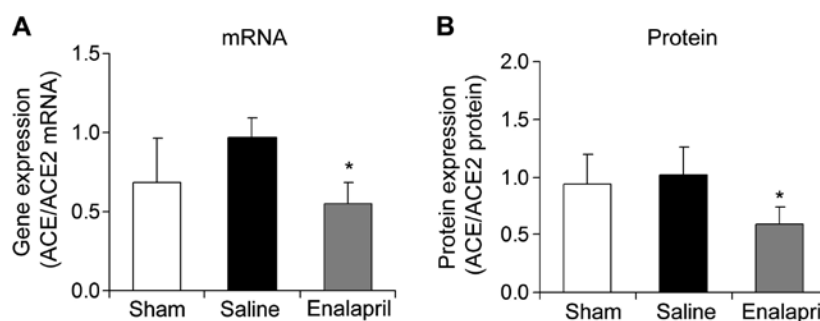

Figure 6. (A and B) Ratio of angiotensin-converting enzyme (ACE) to ACE2 mRNA and protein levels in myocardial tissue post-resuscitation in a swine model of cardiac arrest (CA) and resuscitation. * $P < 0.05$ vs. saline group. $n = 6-9$ /group.

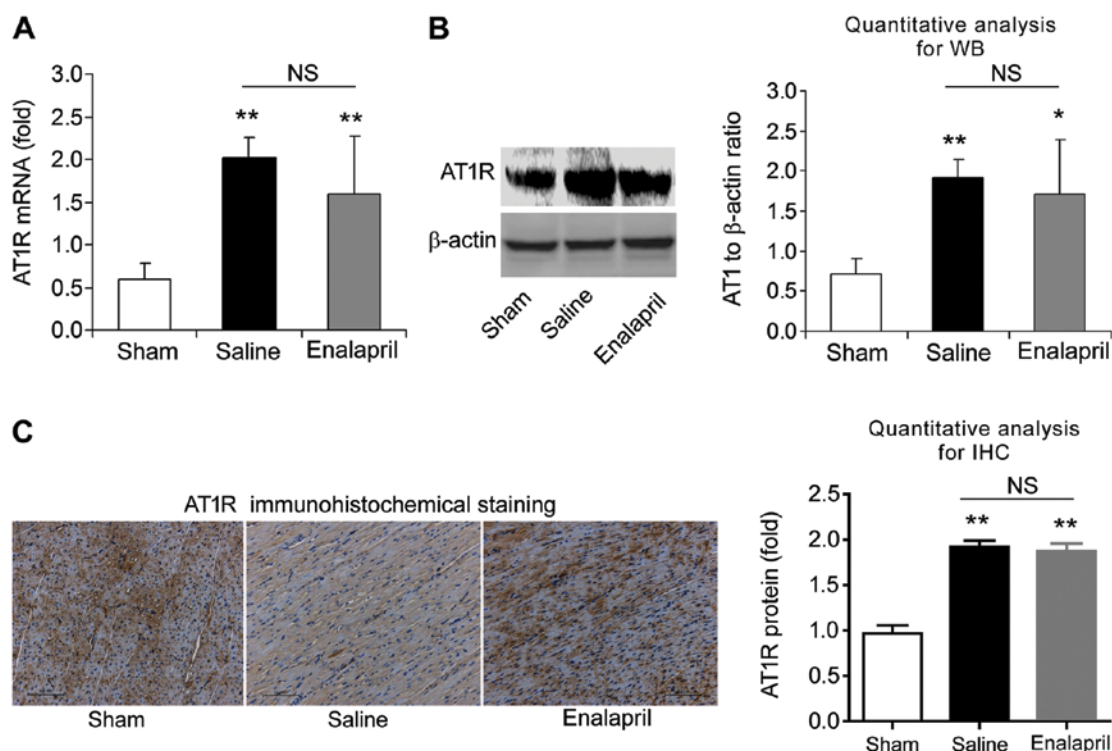

Figure 7. The mRNA and protein levels of angiotensin II type 1 receptor (AT1R) in myocardial tissue post-resuscitation in a swine model of cardiac arrest (CA) and resuscitation. Effects of enalapril on the mRNA and protein levels of AT1R were determined using (A) RT-qPCR, (B) western blot analysis and (C) immunohistochemistry, and compared with the sham and saline-treated groups. * $P < 0.05$ and ** $P < 0.01$ vs. sham group. NS, no significance. $n = 6-9$ /group. Magnification, $\times 200$ in (C).

enhancement of plasma Ang II levels at 4 and 6 h post-ROSC was significantly inhibited by enalapril pre-treatment. By contrast, enalapril pre-treatment did not affect plasma Ang-(1-7) levels. RT-qPCR, western blot analysis and immunohistochemistry assays demonstrated that enalapril pre-treatment successfully suppressed the upregulation of ACE but not ACE2 upon CA and resuscitation. Particularly, we noted that the mRNA ratio of ACE/ACE2 was also decreased by enalapril pre-treatment. Finally, enalapril did not alter the upregulation of AT1R and MAS upon CA and resuscitation. These results demonstrate, for the first time to the best of our knowledge, that pre-treatment with an ACEI protects against myocardial I/R injury post CA and resuscitation, and that inhibition of the ACE/Ang II/AT1R axis may contribute to the cardioprotective effects of enalapril in this context.

The pathophysiology of PCAS is unique from post-arrest brain injury, post-arrest myocardial dysfunction, systemic

I/R response and persistent precipitating pathology (28). Ischemic cerebral injury alone contributes significantly to the high morbidity and mortality in the resuscitated cardiac arrest patient. The myocardial dysfunction associated with PCAS is characterized largely by global hypokinesia and also, ultimately affects the success rate of resuscitation (28). The following molecular mechanisms may contribute to the pathophysiology of myocardial dysfunction in PCAS. Firstly, I/R injury results in a large amount of oxygen free radicals which damage cell membranes and induce the necrosis and apoptosis of myocytes (29). Secondly, intracellular Na^+ accumulation caused by CA leads to cytosolic Ca^{2+} overload through the reverse-mode operation of the sarcolemmal $\text{Na}^+-\text{Ca}^{2+}$ exchanger. Limiting sarcolemmal Na^+ entry during resuscitation from ventricular fibrillation has been shown to prevent the accumulation of excess mitochondrial Ca^{2+} and attenuate myocardial injury (30). Additionally, it

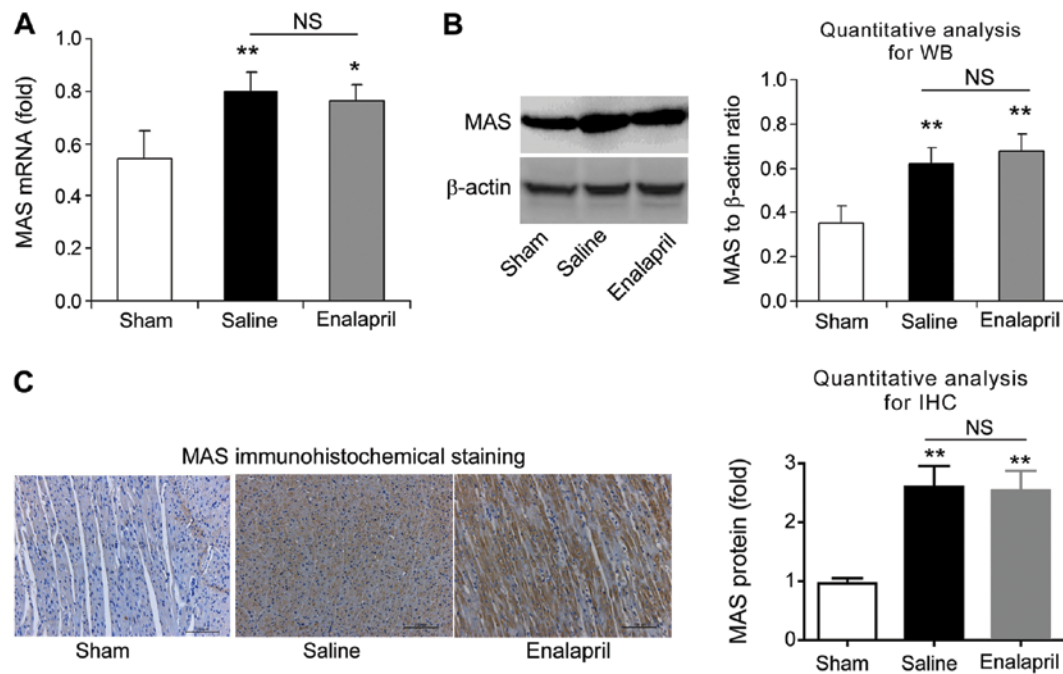

Figure 8. The mRNA and protein levels of MAS receptor in myocardial tissue post-resuscitation in a swine model of cardiac arrest (CA) and resuscitation. Effects of enalapril on the mRNA and protein levels of MAS receptor were determined using (A) RT-qPCR, (B) western blot analysis and (C) immunohistochemistry and compared with the sham and saline-treated groups. * $P < 0.05$ and ** $P < 0.01$ vs. sham group. NS, no significance. $n = 6-9$ /group. Magnification, $\times 200$ in (C).

has become apparent that the endothelium participates in a host of responses elicited by I/R injury in PCAS. Both biochemical and mechanical stimulation of the endothelium elicits the production of several mediators, including endothelium-derived nitric oxide, prostaglandins, antithrombotics and anticoagulants (31).

Enalapril is a long-acting, sulphhydryl-free ACEI with maximal humoral and hypotensive effects at 4-8 h, which remain detectable at 24 h, after a single dose (32). It has been widely prescribed as an anti-hypertensive drug for many years. Previously, the beneficial effect of enalapril on myocardial ischemic injury has been confirmed in animal models of coronary artery ligation (7,33). These studies showed that ACEIs limited myocardial injury and necrosis (7,33). Moreover, a larger scale clinical trial demonstrated that there were significant reductions in the number of enalapril-treated patients developing myocardial infarction or unstable angina (34). Enalapril has also been shown to decrease blood markers of inflammation in patients hospitalized with ischemic symptoms (34). However, there are significant differences between the myocardial ischemic injury induced by coronary artery ligation and CA-resuscitation. Coronary artery ligation always induces local myocardial ischemic injury whereas CA-resuscitation may induce global hypoperfusion that results in acute damage to other organs, such as cerebral I/R injury and kidney I/R injury (9,10). Disruption of the blood-brain barrier and the formation of brain edema after CA-resuscitation are the major factors leading to permanent brain damage (35). However, information regarding the application of ACEIs in patients with CA and resuscitation is limited. Recently, Hoyer *et al* provided evidence that ACE inhibition led to significantly improved myocardial contractility after prolonged CA with Bretschneider's solution (36).

In line with the findings of this study, our data demonstrated that enalapril also successfully decreased myocardial injury in a swine model of CA-resuscitation. The attenuation of ultra-structural injury, plasma cTNI levels and myocardial apoptosis were observed in the heart tissue of the enalapril-treated swine. We suggest that the cardioprotective effects of enalapril are associated with anti-apoptotic activity. Previously, the anti-apoptotic effect of ACEIs or ARBs were illustrated in left anterior descending (LAD) artery ligation-induced local myocardial ischemia (37,38). To the best of our knowledge, our data provides evidence for this effect of ACEIs in a model of CA-resuscitation for the first time.

Some researchers and clinicians have suggested that ACEIs may induce hypoperfusion and therefore be harmful to the myocardium during CA and resuscitation (39,40). For example, a case report by Bjerregaard and Jaffe found that a patient presenting for cerebral aneurysm clipping continued ACEI use on the morning of surgery, and subsequently experienced significant post-induction hypotension that culminated in CA (39). However, Zhang *et al* reported that enalapril did not affect coronary perfusion pressure during the resuscitation period after VF (41). Our data showed that although MAP was slightly decreased, enalapril had no detrimental effect on the survival rate post CA-resuscitation. These results suggest that blockade of the RAAS would not increase the mortality of CA. Clinical investigation has also demonstrated that there was no difference in the incidence of CA between patients treated with ACEIs and without ACEIs (2). Thus, this study supports the notion that the application of ACEIs is a promising therapy in post-resuscitation patients.

The present study further explored the potential effects of enalapril pre-treatment on the RAAS system. The RAAS is composed of a series of hormones and corresponding enzymes.

Angiotensinogen is the precursor molecule of the RAAS and its cleavage product is Ang I, which is converted to Ang II by ACE. Ang II is the major effector of the RAAS through binding to 2 receptor subtypes, AT1R and AT2R. Most detrimental actions of Ang II on the heart are mediated by AT1 (42,43). Ang-(1-7) may be catalyzed by ACE2 from Ang II and activates the MAS receptor to exert vasodilatory, anti-angiogenic, anti-thrombotic and anti-proliferative effects (6). Thus, the balance between the ACE/Ang II/AT1R axis and the ACE2/Ang-(1-7)/MAS axis elegantly modulates cardiovascular biology. An imbalance between these two axes leads to dysfunction of the RAAS, which may underlie the pathophysiology of cardiovascular disorders such as ischemic heart disease, vascular remodeling, hypertension, cardiac failure, atherosclerosis, neointima formation and chronic kidney disease. During these processes, an increased circulating level of Ang II may be a critical adverse factor. In line with previous findings (44), we observed elevations in plasma Ang II and Ang-(1-7) in the saline group; however, enalapril successfully lowered plasma Ang II levels. As a result, we hypothesize that enalapril may protect organs from Ang II-induced cellular damage by suppressing the ACE/Ang II/AT1R axis. By contrast, enalapril did not affect Ang-(1-7) levels, suggesting that ACEIs do not alter plasma Ang-(1-7) levels.

Enalapril reduced the mRNA and protein expression of ACE, as well as the ACE/ACE2 mRNA ratio. The ratio of ACE/ACE2 in myocardial tissue is a marker of RAAS activation (45). Particularly, ACE and ACE2 often go in opposite directions in renal pathological states, and the ACE/ACE2 ratio is a convenient way to reflect this altered pattern (45). It has been demonstrated that the ACE/ACE2 ratio correlated positively with mean blood pressure, fasting blood glucose, serum creatinine, proteinuria and hemoglobin A1c, and inversely correlated with the estimated glomerular filtration rate (34). The ACE/ACE2 ratio may serve as a novel biomarker or independent risk factor relevant for the diagnosis and the prognosis of cardiorenal syndrome (46). An increased ACE/ACE2 ratio in diabetic patients with overt nephropathy suggests that RAAS activation has occurred, which may contribute to renal injury as a result of Ang II accumulation (45,47). Liu *et al* showed that a change in the ACE/ACE2 ratio correlates with the severity of cerulein-induced acute pancreatitis in mice (48). Moreover, the ACE/ACE2 ratio is a potential biomarker for pulmonary disease (49). Consequently, the enalapril-induced attenuation of the local ACE/ACE2 ratio may ultimately contribute to the protective effects of enalapril on myocytes.

There are several limitations of this study. Firstly, we used healthy pigs in this model of CA and resuscitation; however, most humans suffering from CA are at risk of hyperglycemia, hyperlipidemia and arrhythmia. These malfunctions may affect the outcome of enalapril treatment in humans. Secondly, we selected the dose of enalapril according to the findings of previous studies and did not test other dosages and time windows for enalapril pre-treatment in the CA and resuscitation model. In fact, the dosage and time window for enalapril directly determines the therapeutic outcome. Thirdly, enalapril was administered prior to CA to illustrate the protective effects of enalapril against global ischemic injury rather than against limited myocardial tissue ischemia. Whether enalapril would still exert cardioprotective effects post-CA was not evaluated.

In conclusion, our data demonstrate that enalapril protects against myocardial I/R injury in a swine model of CA and resuscitation by suppressing the ACE/Ang II/AT1R axis. These results enhance our understanding of the cardioprotective effects of enalapril targeted against CA-induced global I/R injury.
