Abstract. The present study aimed to evaluate the cardio-protective effects of a Rho-kinase inhibitor, Y-27632, and the underlying mechanisms. A rat model of myocardial ischemia-reperfusion (I/R) injury was generated by ligation of the coronary artery, and global ischemia of isolated rat hearts was conducted using the Langendorff system. Staining with triphenyltetrazolium chloride (TTC) and hematoxylin and eosin was performed to analyze the myocardial infarct size and histopathological alterations of the I/R-induced rat heart. In addition, coronary flow, myocardial contractility and an electrocardiogram were analyzed. The effects of Y-27632 on inflammatory cytokines and cardiac enzymes in the serum were assessed by ELISA. The expression of apoptosis- and inflammation-associated proteins was also analyzed via western blotting. Rats in the Y-27632 group exhibited alleviated myocardial I/R injury according to TTC staining and histopathological diagnosis. Additionally, Y-27632 restored the ST segment. The data of coronary flow and myocardial contractility in isolated rat hearts indicated that Y-27632 improved heart function following I/R. The levels of inflammatory cytokines and cardiac enzymes in the serum were downregulated by Y-27632. Furthermore, apoptosis-associated protein expression in rats and the isolated hearts was effectively inhibited by Y-27632. In conclusion, the findings of the present study indicated that Y-27632 attenuated myocardial injury via inhibiting the activation of the MAPK and NF-κB signaling pathways; thus, apoptosis and the inflammatory response were suppressed.

Introduction

Cardiovascular diseases are associated with high morbidity and mortality rates worldwide. Restoring the blood supply following myocardial ischemia may alleviate ischemic injury; however, this process can promote damage to the ischemic myocardium, which is identified as ischemia-reperfusion (I/R) injury (1). It has been reported that I/R injury induces damage associated with functional impairment of the heart and arrhythmia (2). Therefore, it is important to alleviate I/R injury when treating ischemic heart disease. In clinical settings, drugs including diltiazem, are mainly used in response to I/R injury. A previous study demonstrated that apoptosis and inflammation are involved in the development of I/R injuries (3), whereas anti-inflammatory and antiapoptotic effects have been reported to be associated with myocardial protection (4).

As a serine/threonine protein kinase of the Rho family, Rho-associated protein kinase (ROCK) acts as a molecular switch of the cellular signaling pathway, and may be activated by RhoA. The RhoA/ROCK signaling pathway has been reported to be involved in numerous diseases, including atherosclerosis, cardiac hypertrophy, heart failure and diabetes-associated diseases. RhoA also serves a central role in signal transduction. It has been suggested that activation of the mitogen-activated protein kinase (MAPK) and nuclear factor (NF)-κB signaling pathways is regulated by RhoA/ROCK signaling (5). As a selective Rhokinase inhibitor, (+)-(R)-trans-4-(1-aminoethyl)-N-(4-pyridyl) cyclohexane carboxamide (Y-27632) has been used in numerous experiments (6). Of note, Y-27632 has been observed to exhibit protective effects against I/R cardiac injury in animals (7). Y-27632 has also been reported to suppress the apoptosis of human cardiac stem cells (8). ROCK inhibitors have been demonstrated to protect against I/R injury; however, the underlying molecular mechanism requires further investigation. Therefore, the present study aimed to investigate the pharmacological effects of Y-27632 on I/R-induced heart injury and the potential underlying mechanisms.
Materials and methods

Reagents. Y-27632 was purchased from Tocris Cookson, Ltd. (Bristol, UK). All primary antibodies used in the present study, including anti-RhoA, -ROCK1, -c-Jun N-terminal kinase (JNK), -phosphorylated (P)-JNK, -extracellular signal-regulated kinase (ERK), -P-ERK, -P-P38, -P38, -P-NF-κB, -NF-κB, -inhibitor of NF-κB (IkB), -P-IkB, -B-cell lymphoma 2 (Bcl-2), -Bcl-2-associated X (Bax), -Caspase-3, -Caspase-9 and -GAPDH, were obtained from Cell Signaling Technology, Inc. (Danvers, MA, USA). ELISA kits for the detection of interleukin (IL)-6, tumor necrosis factor (TNF)-α and IL-1β were purchased by R&D Systems, Inc. (Minneapolis, MN, USA). Creatine kinase (CK) and lactate dehydrogenase (LDH) assay kits were obtained from MultiSciences (Lianke) Biotech Co., Ltd. (Hangzhou, China).

Animals. Male Sprague-Dawley rats (8 weeks old; ~250-280 g) were obtained from Beijing Vital River Laboratory Animal Technology Co., Ltd. (Beijing, China) and housed together under a 12-h light/dark cycle, with free access to food and water, at a constant temperature of 22-24˚C and relative humidity of 50±5%. All animal treatments in the present study were performed humanely and following the institutional and national guidelines for ethical animal research. All experimental procedures were conducted according to the guidelines and following approval from the Ethical Committee of Experimental Animal Care at Wenzhou Medical University (Wenzhou, China).

Myocardial I/R model. The rats were anesthetized via 2% isoflurane inhalation prior to establishing the I/R rat model by ligation of the left descending coronary artery, as previously described (9). The rats were anesthetized and restrained; the trachea was then incised and wrapped in catgut for later use. An incision was then made in the skin at the position of the heart, and the underlying ribs were exposed by blunt dissection using image analysis software (Image-Pro Plus version 4.1; Media Cybernetics, Inc., Rockville, MD, USA).

Histological evaluation. The morphology of the myocardial tissues was examined using hematoxylin and eosin (H&E) staining. Following dehydration with 80, 90 and 100% ethanol and n-butanol, the myocardial tissue was waxed in a 60˚C wax box and then embedded in paraffin. Tissue sections (5-μm) were dried at 45˚C and obtained from each paraffin block. The sections were heated at 60˚C for 1 h and dewaxed with xylene. Following hydration, the sections were stained with H&E, dehydrated with gradient ethanol, cleared with xylene and mounted with neutral gum. Images were captured using a light microscope (BX41; Olympus Corporation, Tokyo, Japan).

Western blotting. Total protein was extracted from heart samples and analyzed by western blotting with the specific antibodies described. Briefly, the samples were collected and
homogenized, and then lysed in extraction buffer for 1 h on ice. The total protein content was quantified using a Bicinchoninic Acid protein assay kit (Beyotime Institute of Biotechnology, Nanjing, China). Equal quantities of protein (20 µg) were separated by 8-12% SDS-PAGE and then electrotransferred onto polyvinylidene difluoride (PVDF) membranes, which were blocked with skim milk at room temperature for 2 h. Following blocking, the PVDF membranes were incubated with specific antibodies against RhoA (1:1,000; cat. no. 2117), ROCK1 (1:1,000; cat. no. 4035), P-JNK (1:1,000; cat. no. 9255), JNK (1:1,000; cat. no. 9252), P-ERK (1:1,000; cat. no. 8544), ERK (1:1,000; cat. no. 4348), P-P38 (1:1,000; cat. no. 4511), P38 (1:1,000; cat. no. 8690), P-NF-κB (1:1,000; cat. no. 3033), NF-κB (1:1,000; cat. no. 8242), P-IκB (1:1,000; cat. no. 2859), IκB (1:1,000; cat. no. 4812), Bcl-2 (1:1,000; cat. no. 2764), Caspase-3 (1:1,000; cat. no. 9662), Caspase-9 (1:1,000; cat. no. 9508) and GAPDH (1:2,000; cat. no. 5174; all from Cell Signaling Technology, Inc.) overnight at 4°C. On the second day, the PVDF membranes were incubated with a secondary antibody [horseradish peroxidase-labeled mouse anti-rabbit immunoglobulin (Ig) -G (1:5,000; cat. no. 5127; Cell Signaling Technology, Inc.); and horseradish peroxidase-labeled rabbit anti-mouse IgG (1:5,000; cat. no. 58802; Cell Signaling Technology, Inc.),] at room temperature for 1 h following three washes with tris-buffered saline with Tween-20. Subsequently, the immunoreactive bands were visualized with a gel imaging system (Tanon 5200; Tanon Science and Technology Co., Ltd., Shanghai, China).

**Statistical analysis.** The data are presented as the mean ± standard deviation, and were analyzed by one-way analysis of variance followed by Tukey's post hoc test using GraphPad Prism software 6.0 (GraphPad Software, Inc., La Jolla, CA, USA). P<0.05 was considered to indicate a statistically significant difference.

**Results**

**Effects of Y-27632 on myocardial infarct size.** To determine whether Y-27632 exhibits myocardial protective effects, the infarct size of rat hearts was analyzed by TTC staining. As
Effects of Y-27632 on myocardial histology. To investigate the effects of Y-27632 on myocardial injuries, histopathological alterations of the myocardial tissues were analyzed. As presented in Fig. 1B, extensive inflammatory cells and the notable destruction of myocardial cellular structure were observed in the I/R group compared with the sham group. Additionally, treatment with Y-27632 or Dil markedly attenuated the histological alterations induced by I/R.

Effects of Y-27632 on coronary flow in the I/R-induced isolated heart. As presented in Fig. 2A, the I/R group exhibited significant decreases in the ratio of coronary flow compared with that in the sham group (P<0.01). By contrast, treatment with Y-27632 or Dil led to notable increases in the ratio of coronary flow.

Effects of Y-27632 on myocardial contractility in the I/R-induced isolated heart. Analysis of the ratio of myocardial contractility of isolated rat hearts revealed that the model group exhibited significantly a reduced ratio of contractility following the inhibition of K-H flow compared with that in the sham group (P<0.01). By contrast, treatment with Y-27632 or Dil led to a notable increase in the myocardial contractility (Fig. 2B).

Effects of Y-27632 on myocardial contractility in the I/R-induced isolated heart. As presented in Fig. 3, an increase in ST-segment and a decrease in R-amplitude were observed in the I/R group compared with the sham group; however, these effects were reversed following treatment with Y-27632 or Dil.

Effects of Y-27632 on inflammatory cytokines in the serum. To investigate the potential anti-inflammatory effects of Y-27632, the serum levels of IL-6, TNF-α and IL-1β were measured by ELISA. As presented in Fig. 4A, the levels of IL-6, TNF-α and IL-1β were significantly upregulated in the I/R model group compared with those in the sham group. Treatment with Y-27632 or Dil significantly reduced the levels of inflammatory cytokines compared with those in the I/R group.

Effects of Y-27632 on cardiac enzymes. As representative indicators of myocardial injury, the levels of CK and LDH in the serum were analyzed. As presented in Fig. 4B, the serum levels of CK and LDH were significantly upregulated in the I/R group compared with the those in the sham group (P<0.01, respectively). By contrast, treatment with Y-27632 or Dil effectively suppressed the levels of CK and LDH.

Effects of Y-27632 on the RhoA/ROCK and MAPK/NF-κB signaling pathways, and apoptosis in the I/R-induced heart. To determine the intracellular signaling pathway underlying the myocardial protective effects of Y-27632 in I/R, the RhoA/ROCK and MAPK/NF-κB signaling pathways, and

The data are expressed as the mean ± standard deviation. ##P<0.01 vs. sham/control group; *P<0.05 and **P<0.01 vs. I/R group. I/R, ischemia-reperfusion; Dil, diltiazem; ROCK, Rho-associated protein kinase.
Figure 6. Effects of Y-27632 on the phosphorylation of mitogen-activated protein kinases. Effects in the hearts of (A) left coronary artery ligation rats and (B) Langendorff-perfused rats hearts. The data are expressed as the mean ± standard deviation. **P<0.01 vs. sham/control group; *P<0.05 and ***P<0.01 vs. I/R group. I/R, ischemia-reperfusion; Dil, diltiazem; JNK, c-Jun N-terminal kinase; ERK, extracellular signal-regulated kinase; P-, phosphorylated.
apoptosis were investigated. Upregulated expression levels of RhoA and ROCK1 (Fig. 5A and B) and increased phosphorylation of ERK1/2, JNK and P38 proteins (Fig. 6A and B) were observed in the I/R group; however, treatment with Y-27632 or Dil treatment notably reversed the effects of I/R on the expression of the aforementioned proteins.

To further investigate the downstream mechanism underlying the effects of Y-27632 on the I/R-induced heart in rats, the expression levels of P-1κB and P-NF-κB were determined (Fig. 7A and B). Western blot analysis demonstrated upregulated expression of P-1κB and P-NF-κB in the model group compared with the sham group. Following treatment with Y-27632 or Dil, significantly suppressed expression levels of P-1κB and P-NF-κB were detected. These results indicated that the inhibition of ROCK1 may prevent the activation of NF-κB.

As presented in Fig. 8A and B, the expression levels of apoptosis-associated proteins were detected to investigate the mechanism underlying the effect of Y-27632 on cardiomyocyte apoptosis. I/R injury markedly increased the expression of Bax, Caspase-3 and Caspase-9, which was associated with reduced expression levels of Bcl-2. Treatment with Y-27632 or Dil markedly reversed the effects of I/R injury on the expression of the aforementioned proteins. These results indicated that the inhibition of ROCK1 may suppress apoptosis.

Discussion

At present, the prevalence and mortality rates of cardiovascular diseases have significantly increased with the aging of populations and alterations in lifestyle (10). Cardiovascular diseases are the main cause of mortality in the Chinese population and account for >40% of the reported mortality rate, which may increase in the next 10 years (11). The therapeutic approaches and agents available have markedly improved; however, the treatment of myocardial ischemia
remains ineffective. Therefore, further investigation into treating myocardial ischemia is required. In the present study, the cardioprotective effects of Y-27632 were determined via TTC and H&E staining, and analyzing ST-segment elevations. These observations were supported by analyzing coronary flow and myocardial contractility.

The Rho/ROCK signaling pathway has been associated with the growth, proliferation and differentiation of cells, which are widely involved in various pathophysiological processes. Rho A is a small GTP-binding protein, whereas ROCK is the downstream effector protein of Rho A (12). ROCK is a serine/threonine protein kinase involved in the regulation of numerous cellular functions, including migration, contraction and adhesion. Blood pressure, cardiac hypertrophy, heart failure and other cardiovascular diseases have been associated with the activity of ROCK (13). As the downstream molecule of ROCK, NF-κB is a nuclear transcription factor with multi-directional regulation, and regulates the expression of genes associated with immune, stress and inflammatory responses. It has been reported that I/R of the heart can induce the overexpression of inflammatory and apoptotic cytokines (14-16). Increasing evidence has indicated that the Rho/ROCK/NF-κB signaling pathway serves important roles in cardiomyocytes and experimental myocardial infarction (17-19). In the present study, it was determined that Y-27632 successfully inhibited the Rho/ROCK signaling pathway and may lead to suppression of the activation of NF-κB.

MAPKs, including P38 MAPK, JNK and ERK, serve crucial roles in cell signaling transduction (17). Upon stimulation by a variety of stimuli, MAPKs can regulate the growth, proliferation, differentiation and survival of cells. As widely known stress-activated protein kinases, JNK and P38 MAPK promote cellular survival or apoptosis (18). It has been suggested that JNKs induce apoptosis caused by I/R, inflammation or oxidative stress (19). Sustained activation of ERK1/2 in I/R has been reported previously. Furthermore, ROCK has been determined to be associated with the activation of MAPK in cardiovascular diseases. The findings of the present study suggested that the inhibition of ROCK effectively suppressed the phosphorylation of MAPKs.

Myocardial I/R can induce apoptosis in heart tissues. Myocardial infarction has been reported to increase cell permeability, promote the caspase cascade and lead to the apoptosis of cardiomyocytes (20). The harmful stimulus of myocardial infarction promotes Caspase-9 via an apoptotic signaling pathway and induces Caspase-3, a common downstream effector involved in the apoptotic signaling pathway and with a central role in this process. In addition, Bax and Bcl-2 of the Bcl-2 family are the most important regulatory genes in apoptosis. Numerous studies have suggested that Bcl-2, Bax, Caspase-3
and Caspase-9 are involved in the pathogenesis of myocardial I/R injury. The results of the present study revealed that Y-27632 markedly prevented I/R-induced apoptosis in the rat heart.

In conclusion, the present study demonstrated that Y-27632, a ROCK inhibitor, markedly ameliorated myocardial I/R-induced injury. The protective effects may be due to inhibited MAPK/NF-κB signaling activation; thus, apoptosis and the inflammatory response are suppressed. The findings of the present study may provide novel insight into potential treatments for cardiovascular diseases; however, further investigation is required.
