Abstract. To aim of the present study was to determine whether Tanshinone IIA (Tan IIA) inhibits lipopolysaccharide (LPS)-induced inflammation in vascular smooth muscle cells (VSMCs) from rats and elucidate the underlying molecular mechanism. VSMCs were primarily cultured and then treated with LPS (1 µg/l) and Tan IIA (25, 50 and 100 µmol/l) for 24 h. Monocyte chemoattractant protein (MCP)-1, interleukin (IL)-6 and tumor necrosis factor (TNF)-α levels were detected by ELISA and reverse transcription-quantitative polymerase chain reaction. Nitric oxide (NO) production was measured using the Griess reaction. The expression of Toll-like receptor 4 (TLR4), nuclear factor (NF)-κB (p65), and inducible NO synthase (iNOS), and the phosphorylation of transforming growth factor-β-activated kinase 1 (TAK1) were detected by western blot analysis. Tan IIA inhibited the LPS-induced expression of MCP-1, IL-6, and TNF-α in a concentration-dependent manner and inhibited iNOS-mediated NO production. In addition, Tan IIA suppressed the expression of TLR4, the phosphorylation of TAK1, and the nuclear translocation of NF-κB (p65). The anti-TLR4 antibody and TAK1 inhibitor 5Z-7-oxozeaenol partially attenuated the LPS-induced expression of proinflammatory cytokines. In conclusion, Tan IIA inhibits LPS-induced inflammatory responses in VSMCs in vitro through the partial suppression of the TLR4/TAK1/NF-κB signaling pathway.

Introduction

A long-lasting and low-grade inflammatory response may serve a critical role in the pathogenesis of atherosclerosis, a multi-pathogenic process that occurs within arterial inner and middle walls (1,2). In addition to macrophages, vascular smooth muscle cells (VSMCs) contribute to the progression of atherosclerosis by upregulating inflammatory factors and pathological proliferation (3). Lipopolysaccharides (LPS) are primarily located on the outer membrane of Gram-negative enteric bacteria and can increase the expression of various types of inflammation-associated cytokines, including monocyte chemoattractant protein (MCP)-1, interleukin (IL)-6 and tumor necrosis factor (TNF)-α in VSMCs (4,5). These proinflammatory factors have all been proven to promote the progression of atherosclerosis and increase the number of vulnerable atherosclerotic plaques in several clinical trials (6). Therefore, controlling excessive inflammatory responses, especially inhibiting the proinflammatory cytokines expressed by VSMCs, may be an effective way to suppress the progression of atherosclerosis and enhance atherosclerotic plaque stability.

The Toll-like receptor (TLR) family are pattern recognition receptors that recognize pathogen-associated molecular patterns. A key member of this family is TLR4, which may be associated with the innate and adaptive immunity caused by various stimulants, such as LPS, low-density lipoprotein and heat shock protein (7). Initially, TLR4 was revealed to activate the host defense against invasive infection, but more recent evidence has indicated that activation of TLR4 contributes to the progression of atherosclerosis by inducing excessive inflammation (8). TLR4 overexpression has been observed in atherosclerotic plaques in human and animal models, and was accompanied with an increase in various pro-inflammatory factors, including MCP-1, IL-1β and IL-6 (9,10). By contrast, suppression of TLR4 activation inhibited the progression of atherosclerotic plaques in TLR4 knockout models (11). TGF-β-activated kinase 1 (TAK1) belongs to the mitogen-activated protein kinase (MAPK) family and was initially observed to activate the phosphorylation of MAPK induced by morphogenetic protein and transforming growth factor
As a downstream molecule in the TLR4 signaling pathway, TAK1 can induce the phosphorylation of inhibitor of nuclear factor (NF)-κB kinase (IKK) and then cause NF-κB activation, which may be a key mediator of various inflammatory responses. A previous study has suggested that inhibition of TAK1 activation suppresses LPS-induced inflammation (13).

Tan IIA, which may be beneficial for the treatment of coronary heart disease. The aim of the present study was to define unknown molecular mechanisms that underpin the anti-inflammatory effects of TAK1. Hence, we hypothesized that inhibition of TAK1 activation might suppress inflammation in vivo.

Materials and methods

Reagents. Tan IIA was obtained from the National Institute for the Control of Pharmaceutical and Biological Products (Beijing, China). The purity of Tan IIA was 99%. Dulbecco’s modified Eagle’s medium (DMEM) and fetal bovine serum (FBS) were provided by Gibco (Thermo Fisher Scientific, Inc., Waltham, MA, USA). Penicillin, streptomycin, Tris-Buffered saline-0.5% Eagle’s medium (DMEM) and fetal bovine serum (FBS) were purchased from Sigma-Aldrich (Merck KGaA, Darmstadt, Germany). Calbiochem (Merck KGaA, Germany) and Gibco (Thermo Fisher Scientific, Inc., Waltham, MA, USA) were used to treat cardiovascular diseases, including coronary heart disease (14). Tan IIA is an important constituent of Tans which are abietane-type norterpenoid quinone natural products. Tan IIA has been shown to have various pharmacological effects, including anti-proliferation (15), anti-inflammation (16), anti-oxidation (17), and anti-tumor influences (18). Fan et al (19) described a Tans anti-inflammatory effect on LPS-induced RAW264.7 cells, where the TLR4-MyD88-NF-κB signaling pathway was shown to impede microRNA expression and regulate the production of a series of cytokines. However, it is unknown if Tan IIA can inhibit LPS-induced inflammation in VSMCs or if Tan IIA’s anti-inflammatory effects are associated with the TLR4/TAK1/NF-κB signaling pathway. Therefore, the aim of the present study was to define unknown molecular mechanisms that underpin the anti-inflammatory effects of Tan IIA, which may be beneficial for the treatment of coronary heart disease.

Cell viability assay. VSMCs were seeded at a density of 5,000 cells/well in 96-well plates containing 100 μl DMEM with 15% FBS and incubated for 12 h. Tan IIA was dissolved in dimethylsulfoxide (DMSO). Cell viability was determined by an MTT reduction assay. The cells were either treated with Tan IIA at the indicated concentrations (0, 6.25, 12.5, 25, 50, 100 and 200 μmol/l) for 24 h at 37°C, or cells were pretreated with Tan IIA (0, 6.25, 12.5, 25, 50, 100 and 200 μmol/l) and then stimulated with LPS (1 μg/ml) for 24 h at 37°C. The medium was replaced and cells were then incubated with MTT solution (5 mg/ml) for 4 h at 37°C. The dark blue formazan crystals that formed within and on intact cells were solubilized with 150 μl of DMSO, and then the absorbance was measured at 490 nm on a microplate reader (Bio-Rad Laboratories, Inc., Hercules, CA, USA).

ELISA. VSMCs were seeded at a density of 5x10⁶ cells/well in 6-well plates. Cells were pretreated with Tan IIA (5, 10 or 30 μmol/l) for 1 h, then LPS (1 μg/ml) was added to the VSMC culture medium for 24 h. VSMCs were pretreated with an antibody against TLR4 (1:250; cat. no. 542-0006), the TAK1 inhibitor SZ-7-oxozaeanol (0.5 μmol/l), and PDTC (100 μmol/l) for 1 h at 37°C and were then incubated with LPS (1 μg/ml) for an additional 24 h at 37°C. The medium was collected when the cells reached 80-95% confluence, and cells were incubated for 12 h prior to subsequent experiments.

Measurement of NO production. The accumulation of nitrite, a stable precursor of NO in culture medium, was measured using the aforementioned ELISA kits (MCP-1 kit: cat. no. BYK-1021R; IL-6 kit: cat. no. EK-0411; TNF-α kit: cat. no. BK-0657) at 37°C, according to the manufacturer’s instructions.

Reactive oxygen species (ROS) production measurement. The 2,7’-dichloro-dihydro-fluorescein diacetate (DCFH-DA) assay
kit was purchased from Biyuntian Biotechnology Research Institute (Jiangsu, China; cat. no. S0076) and was used to measure intracellular ROS levels, based on the ROS-dependent oxidation of DCFH to highly fluorescent dichlorofluorescein. DCFH (10 mmol/l) was dissolved in methanol and then diluted by a factor of 500 in Hanks' balanced salt solution (HBSS) to produce a 20 μmol/l DCFH solution. The cells were incubated with DCFH-DA for 1 h at 37°C and then treated with HBSS containing Tan II A (25, 50 or 100 μmol/l) or LPS (1 μg/ml) for a further 90 min at 37°C. Fluorescence was measured immediately at a wavelength of 485 nm for excitation and 528 nm for emission on an iMark™ Microplate Absorbance Reader (Bio-Rad Laboratories, Inc.).

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR). Once the cells were treated with Tan II A at the indicated concentrations (25, 50 and 100 μmol/l) for 24 h at 37°C, total RNA was extracted using a TransZol reagent and DNA was removed using a DNA-free kit (Ambion; Thermo Fisher Scientific, Inc.). The quality of mRNA was verified by performing denaturing agarose gel electrophoresis containing 1.5% formaldehyde. The total RNA concentration and purity were determined through UV-Vis spectroscopy using the Bio-Rad SmartSpec 5000 system (Bio-Rad Laboratories, Inc.). To synthesize cDNA, 1 µg of total RNA was used in a 20 µl reaction using oligo(dT)18 Primer and EasyScript Reverse Transcriptase (Fisher Scientific, Inc.). Primer and EasyScript Reverse Transcriptase kit (Thermo Fisher Scientific, Inc.). Reverse transcription reaction conditions were as follows: 37°C for 15 min, then 85°C for 5 sec with the reverse transcription reagent and enzyme, and then kept at 4°C. Primers for rat MCP-1, IL-6, TNF-α, iNOS, TLR4, p47phox and β-actin were chosen using the Beacon designer v4.0 (Premier Biosoft International, Palo Alto, CA, USA; Table I). β-actin was used as an endogenous control. The mRNA levels of MCP-1, IL-6, TNF-α, TLR4, iNOS, and β-actin were performed using 2X Power Tag PCR MasterMix and SYBR-Green (Beijing Transgen Biotech Co., Ltd.), and the ABI PRISM 7000 sequence detection PCR system (Applied Biosystems; Thermo Fisher Scientific, Inc.). The qPCR thermocycling conditions for MCP-1, IL-6, TNF-α, TLR4, iNOS, and β-actin were as follows: 94°C for 5 min, 94°C for 10 sec, 60°C for 20 sec and 72°C for 30 sec, followed by 40 cycles of denaturation for 15 sec at 72°C, annealing for 90 sec at 40°C and extension from 60 to 94°C, followed by 1°C for 1 sec. A single melting curve peak confirmed the presence of a single product. Results were expressed as fold differences relative to β-actin using the 2ΔΔCq method (23).

Western blot analysis. Following cell treatment with Tan II A at the indicated concentrations (25, 50 and 100 μmol/l) for 24 h at 37°C, VSMC lysates were prepared with 200 μl of ice-cold lysis buffer (pH 7.4, 50 mmol/l HEPEES, 5 mol/l EDTA, 100 mmol/l NaCl, 1% Triton X-100, and protease inhibitor cocktail; Roche Diagnostics GmbH, Mannheim, Germany) in the presence of phosphatase inhibitors (50 mmol/l sodium fluoride, 1 mmol/l sodium orthovanadate, 10 mmol/l sodium pyrophosphate and 1 mmol/l microcystin). The activated NF-κB (p65) protein, located in the nucleus, was extracted using the Pierce NE-PER Nuclear and Cytoplasmic Extraction kit (Pierce; Thermo Fisher Scientific, Inc.). A bicinchonic acid protein assay kit was used to determine protein concentrations. A total of 30 μg protein was loaded per lane, then samples were separated by 10% SDS-PAGE and transferred onto a polyvinylidene difluoride membrane in a semi-dry system (Bio-Rad Laboratories, Inc.), which was blocked with 5% fat-free milk in TBST buffer (20 mmol/l Tris-HCl, 137 mmol/l NaCl and 0.1% Tween-20) for 120 min at 37°C. Membranes were then incubated with primary antibodies against TLR4 (1:500; cat. no. sc-2213), TAK1 (1:400; cat. no. sc-2501), p-TAK1 (1:500; cat. no. sc-1152), p47phox (1:400; cat. no. sc-0032), SMA (1:100; cat. no. sc-SC19483), OPN (1:100; cat. no. sc-03652), (1:100; cat. no. sc-0096), β-actin (1:2,000; cat. no. sc-21764), histone (1:1,000; cat. no. sc-1179), p-β-Actin (1:100; cat. no. sc-89320) and p-IkBα (1:100; cat. no. sc-2501) at 4°C overnight at 37°C, following which membranes were washed and then incubated with secondary antibodies (1:5,000; anti-rabbit HRP-conjugated; cat. no. sc-276002; anti-mouse; HRP-conjugated; cat. no. sc-450039) for 110 min at 37°C. The optical densities of bands were quantified using the ECL kit (Sigma-Aldrich; Merck KGaA) and Gel-Pro Analyzer software version 4.0 (Media Cybernetics, Inc., Rockville, MD, USA). β-actin or histone were used as the endogenous control, and the results were expressed relative to their corresponding control and ultimately as fold differences compared with the control.

Statistical analysis. Results are expressed as the mean ± standard error of the mean of six experiments. Differences between groups were assessed by one-way analysis of variance followed by least significant difference post hoc tests. Statistical tests were performed using SPSS 16.0 software (SPSS, Inc., Chicago, IL, USA). P<0.05 was considered to indicate a statistically significant difference.

Table I. Primers used for reverse transcription-quantitative polymerase chain reaction analysis.

IL-6, interleukin-6; TNF-α, tumor necrosis factor-α; MCP-1, monocyte chemotactic protein 1; iNOS, inducible nitric oxide synthase; TLR4, Toll-like receptor 4.
Results

Cytotoxicity of Tan IIA in VSMCs. Cells were treated with different concentrations of Tan IIA (0-200 µmol/l) or LPS (1 µg/ml) for 24 h and then cytotoxicity was measured by an MTT assay. As shown in Fig. 1, 0-100 µmol/l Tan IIA was not cytotoxic against VSMCs with or without LPS (1 µg/ml).

Tan IIA inhibits LPS-induced VSMC phenotypic switching. VSMC phenotypic switching is involved in the LPS-induced inflammatory response. When VSMCs transform from the contractile phenotype to the synthetic phenotype, they produce lower levels of contractile proteins (24), such as α-SMA, and higher levels of OPN. As shown in Fig. 2A, following VSMC treatment with LPS (1 µg/ml) for 24 h, the protein expression of α-SMA decreased; however, OPN levels increased. Pretreatment with Tan IIA attenuated the downregulation of α-SMA and suppressed the upregulation of OPN in LPS-stimulated VSMCs, in a concentration-dependent manner. Similar results were obtained from mRNA level measurements via RT-qPCR (Fig. 2B).

Tan IIA inhibits the LPS-induced expression of MCP-1, IL-6, and TNF-α in VSMCs. A significant increase in the expression of MCP-1, IL-6, and TNF-α in the conditioned media of VSMCs treated with LPS (1 µg/ml) for 24 h was observed. Treatment with Tan IIA inhibited the LPS-induced protein expression of MCP-1, IL-6, and TNF-α in VSMCs in a concentration-dependent manner (Fig. 3A-C). In addition, Tan IIA also reduced the mRNA expression of MCP-1, IL-6, and TNF-α in LPS-stimulated VSMCs in a concentration-dependent manner (Fig. 3D-F). However, treating cells with Tan IIA (100 µmol/l) alone did not affect either the mRNA or protein expression of these proinflammatory cytokines.

Inhibitory effect of Tan IIA on iNOS-mediated NO production in LPS-stimulated VSMCs. Results from the Griess assay revealed that Tan IIA inhibited LPS-induced NO production in VSMCs in a concentration-dependent manner. However, treating the cells with Tan IIA (100 µmol/l) alone did not affect NO production (Fig. 4). To investigate how Tan IIA decreased LPS-induced NO production, the expression of iNOS was measured. As shown in Fig. 4A and B, Tan IIA reduced the LPS-induced expression of iNOS at the mRNA and protein levels in a concentration-dependent manner. Treatment with Tan IIA alone did not affect the mRNA or protein expression of iNOS when compared with control. Similar results were observed when measuring the NO levels (Fig. 4C). These results suggest that iNOS activation may serve a role in the inhibitory effects of Tan IIA on LPS-induced NO production in VSMCs.

Tan IIA downregulates p47-phox and decreases ROS levels. p47-phox protein (Fig. 5A) and mRNA (Fig. 5B) expression, and ROS production (Fig. 5C) in cultured VSMCs were significantly increased by stimulation with LPS; this effect was dose-dependently inhibited by co-treatment with Tan IIA.

Associations between the inhibitory effect of Tan IIA on LPS-induced inflammation and TLR4 expression in VSMCs. As shown in Fig. 6A and B, LPS (1 µg/ml) treatment significantly increased the mRNA and protein expression of TLR4. Pretreatment with Tan IIA inhibited the LPS-induced expression of TLR4 at the mRNA and protein level in VSMCs (Fig. 6A and B). Treating VSMCs with Tan IIA (100 µmol/l) alone did not affect the expression of TLR4 (Fig. 6A and B). Next, the present study explored if the anti-inflammatory effect of Tan IIA on the LPS-induced expression of proinflammatory cytokines may function partially through TLR4 in VSMCs. Cells were treated with or without anti-TLR4 neutralizing antibody (8 µg/ml) for 1 h, and then Tan IIA (100 µmol/l) was added and incubated for 1 h. This was followed by LPS (1 µg/ml) stimulation in VSMCs for 24 h. The TLR4 inhibitor and Tan IIA partially inhibited the LPS-induced increase in the levels of p-TAK1 (Fig. 6C), MCP-1 (Fig. 6D), TNF-α (Fig. 6E), IL-6 (Fig. 6F), and NO (Fig. 6G) in VSMCs. These results indicate that the inhibitory effect of Tan IIA on LPS-induced inflammation may be partially dependent on TLR4 in VSMCs.
To explore which intracellular signaling pathway downstream of TLR4 is involved in the inhibitory effect of Tan IIA on LPS-induced inflammation, the phosphorylation of TAK1 was detected in LPS-stimulated VSMCs. As shown in Fig. 7, treating VSMCs with different concentrations of Tan IIA (25, 50 and 100 µmol/l) alone did not affect the phosphorylation of TAK1. However, treatment with LPS (1 µg/ml) for 30 min significantly increased the levels of p-TAK1 in VSMCs (Fig. 7B). Pretreating the cells with Tan IIA attenuated the LPS-induced phosphorylation of TAK1 in a concentration-dependent manner (Fig. 7A and B). To determine if the inhibitory effect of Tan IIA on LPS-induced inflammation is dependent on the reduced expression of p-TAK1, the VSMCs were pretreated with or without 5Z-7-oxozeaenol (0.5 µmol/l), which is a specific inhibitor of TAK1 activation. The results confirmed that 5Z-7-oxozeaenol significantly decreased p-TAK1 (Fig. 7B). In addition, 5Z-7-oxozeaenol and Tan IIA partially inhibited the LPS-induced expression of MCP-1, IL-6, TNF-α and NO in VSMCs (Fig. 7C-F). These results suggest that the reduction in p-TAK1 levels induced by Tan IIA may contribute to its anti-inflammatory influence on LPS-stimulated VSMCs.

**Discussion**

The present study demonstrated that Tan IIA inhibits LPS-induced MCP-1, IL-6, TNF-α and iNOS-mediated NO production in VSMCs in vitro. Tan IIA also reduced the LPS-induced expression of TLR4 and TAK1 and reduced the nuclear translocation of NF-κB in a concentration-dependent manner. These results provide a novel association between the anti-inflammatory effect of Tan IIA and the TLR4/TAK1/NF-κB signaling pathway in LPS-stimulated VSMCs.

Multiple factors have been shown to contribute to the progression of atherosclerosis, but chronic low-grade inflammation may be a critical factor in the acceleration of atherosclerosis progression and plaque instability. Various inflammation-associated factors contribute to this process (1). MCP-1 is a potential monocyte chemoattractant cytokine that can induce the migration of monocytes and macrophages to the intima of the arterial walls and accelerate their development into foam cells (26). LPS is a powerful pro-inflammatory
factor that can induce the expression of various inflammation-associated cytokines, including MCP-1, IL-6 and TNF-α, in VSMCs (4). In addition, there is a growing body of evidence that indicates that there is a strong correlation between LPS and atherosclerosis (27). Tan IIA has been reported to have diverse pharmacological effects, including anti-inflammation, anti-apoptosis, and regulation of the immune response (28). Previous studies have indicated that Tan IIA may inhibit the LPS-induced expression of inflammation-associated cytokines in various cell types (19,29,30). In the present study, LPS significantly increased the expression of MCP-1, IL-6, and TNF-α in VSMCs, which is consistent with a previous study (4). However, Tan IIA treatment could attenuate the LPS-induced expression of inflammation-associated cytokines in a dose-dependent manner, which may be a potential mechanism of the anti-inflammatory activity of Tan IIA. In addition, Tan IIA also inhibited the oxidized-low-density lipoprotein-induced inflammatory response in various organs (31), which suggests that Tan IIA has multiple anti-inflammatory activities against more than just LPS.

NO is mainly produced by the endothelium of the arterial walls, and it serves an important role in regulating inflammation.
throughout the process of atherosclerosis (32). While NO is also synthesized by neuronal NOS and endothelial NOS, NO produced by iNOS is the chief contributor to the regulation of immunomodulatory activity (33). Although NO produced by the endothelium may exhibit some beneficial effects that protect endothelial function, high concentrations of NO have...
been revealed to accelerate the progression of atherosclerosis by increasing oxidative stress (34). In addition to atherosclerosis, the overproduction of NO has also been shown to contribute to the progression of various inflammation- and immune-associated diseases, such as Alzheimer's disease (35) and Crohn's disease (36). Previous studies have demonstrated that inhibiting NO production through the use of an inhibitor of iNOS or by knockout of the iNOS gene can reduce the area of atherosclerotic plaques and attenuate plaque vulnerability in high fat diet-fed ApoE−/− mice (37). Therefore, in the present study, the effect of Tan IIA on iNOS-mediated NO production was investigated. Previous studies have demonstrated that Tan can inhibit LPS-induced and iNOS-mediated NO production in macrophages and endothelium (38). In the present study,
Tan IIA significantly inhibited LPS-induced NO production, which was accompanied by a reduction in iNOS expression. These results suggest that Tan IIA suppresses iNOS-mediated NO production in LPS-stimulated VSMCs, which may provide a novel molecular mechanism for the cardiovascular protective effect of Tan IIA.

Previous evidence has demonstrated that the activation of TLR4 serves an important role in the acceleration of atherosclerosis by inducing an excessive inflammatory response (9). In human and animal models, an increase in TLR4 expression has been observed in atherosclerotic plaques, which was accompanied by an overexpression of various inflammation-associated factors (39). Our previous study also demonstrated that LPS increases the expression of TLR4 in VSMCs (4). However, when given the same high-cholesterol diet, TLR4-knockout mice exhibited a reduction in

Figure 7. Associations between the inhibitory effect of Tan IIA on LPS-induced inflammation and TAK1 activation in VSMCs. (A) One group of VSMCs were only treated with Tan IIA (25, 50 and 100 µmol/l) for 30 min; (B) another group of cells were pretreated with the indicated concentrations of Tan IIA (25, 50 and 100 µmol/l) for 1 h and then stimulated with LPS (1 µg/ml) for a further 30 min. The levels of p-TAK1 was measured by western blotting. Cells were pretreated with 5Z-7-oxozeaenol (0.5 µmol/l), Tan IIA (100 µmol/l), or 5Z-7-oxozeaenol (0.5 µmol/l) plus Tan IIA (100 µmol/l) for 1 h and then stimulated with LPS (1 µg/ml) for a further 24 h. The protein expression of (C) MCP-1, (D) TNF-α and (E) IL-6 was measured by an ELISA assay. (F) NO production was detected by the Griess assay. Data are presented as mean ± standard error of the mean from six independent experiments. #P<0.001 vs. control; **P<0.01 and ***P<0.001 vs. LPS; &P<0.05 vs. LPS+5Z-7-oxozeaenol. Tanshinone IIA; VSMCs, vascular smooth muscle cells; LPS, lipopolysaccharide; NO, nitric oxide; IL-6, interleukin-6; TNF-α, tumor necrosis factor-α; MCP-1, monocyte chemoattractant protein 1; p-, phosphorylated; TAK1, transforming growth factor-β-activated kinase 1; 5Z-7, 5Z-7-oxozeaenol.
Figure 8. Tan IIA inhibits LPS-induced NF-κB activation in VSMCs. VSMCs were pretreated with the indicated concentrations of Tan IIA (25, 50 and 100 µmol/l) for 1 h and then stimulated with LPS (1 µg/ml) for a further 24 h (for NF-κB) or 6 h (for p-IkBα). The protein expression of (A) NF-κB (p65) in nuclei and (B) p-IκBα were measured by western blotting, in which histone and β-actin were used as internal controls, respectively. Data are presented as the mean ± standard error of the mean of six independent experiments. *P<0.001 vs. control; **P<0.01 and ***P<0.001 vs. LPS. Tanshinone IIA; VSMCs, vascular smooth muscle cells; LPS, lipopolysaccharide; NF-κB, nuclear factor-κB; p-, phosphorylated; lIkBα, inhibitor of nuclear factor-κB; nuc, nuclear; cyt, cytoplasmic.

As an important downstream molecule, TAK1 serves a critical role in the TLR-mediated inflammatory signaling pathway. Once LPS binds to the CD14/TLR4 complex, TLR4 is activated. Then, Myd88 induces the phosphorylation of IL-1 receptor-associated kinase 4 (IRAK4) and IRAK1, which results in the phosphorylation of TAK1 (41). Activated TAK1 induces the phosphorylation of MAPKs and IKKs, which are the main factors that regulate NF-κB activation (42). Tans have been shown to inhibit the LPS-induced activation of NF-κB by reducing TAK1 expression in macrophages (19). In addition, a previous study evaluated the effects of Tan IIA on atherosclerotic vulnerable plaque stability (43). Tans were reported to also decrease NF-κB activation in VSMCs, which in turn inhibited VSMC proliferation and migration (43). As a conventional regulator of NF-κB, these results indicated that TAK1 may also be involved in the mechanisms underlying NF-κB inactivation by Tan IIA in VSMCs. In the present study, Tan IIA induced effects similar to those of the TAK1 inhibitor. Tan IIA attenuated the LPS-induced expression of p-TAK1 in a concentration-dependent manner and inhibited the LPS-induced expression of MCP-1, IL-6, TNF-α, and NO in VSMCs. These results suggest that the inhibition of TAK1 activation may be involved in the anti-inflammatory effect of Tan IIA in LPS-stimulated VSMCs.

NF-κB is a ubiquitously expressed nuclear transcription factor that is considered to be associated with inflammation, especially in the expression of cytokines. Activation of NF-κB occurs when it is isolated from IκBα. Once IκBα is phosphorylated, it degrades and allows NF-κB to become activated, and then NF-κB is translocated from the cytosol into the nucleus where it can control DNA transcription. Following cell stimulation with LPS, the level of p-IκBα was increased while the level of total IκBα was decreased, which was consistent with the results of some previous studies (44,45). Many signaling pathways result in NF-κB phosphorylation, which causes NF-κB to hydrolyze into several subunits (46). One of the subunits is P65, which translocates to the nucleus to bind to DNA. It then upregulates the expression of cytokines, including MCP-1, IL-6, TNF-α, and NO (47). Several studies have indicated that NF-κB may serve an important role in LPS-induced inflammation in macrophages and VSMCs (48,49). As a downstream molecule of TAK1, a reduction in NF-κB may contribute to the anti-inflammatory mechanism of Tan IIA. In the present study, it was observed that pretreatment with Tan IIA attenuated the LPS-induced nuclear translocation of NF-κB (p65) in VSMCs in a dose-dependent manner, which suggests that Tan IIA may inhibit LPS-induced NF-κB activation in VSMCs.

In conclusion, the present study demonstrated the anti-inflammatory properties of Tan IIA in VSMCs by inhibiting MCP-1, IL-6, TNF-α, and NO. These effects may be mediated by downregulating TLR4 and inhibiting TAK1, which consequently leads to the inhibition of NF-κB activation and eventually the suppression of its target genes. The present
study provided a novel experimental basis for using Tan IIA as a therapeutic agent to treat chronic inflammation-mediated diseases, especially atherosclerosis.

Acknowledgements

The authors would like to thank Professor Li Ling (Department of Cardiology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, Henan, China) for assisting with the experimental lab work.

Funding

The present study was supported by the Youth Foundation of The First Affiliated Hospital of Zhengzhou University (grant no. YFFAHZZ 2015020105).

Availability of data and materials

All data generated or analyzed during this study are included in this published article.

Authors' contributions

HYL conceived and designed the study. ZM conducted the majority of the experiments and wrote the paper. CYS, ST and XHY performed the experiments. All authors read and approved the final manuscript.

Ethics approval and consent to participate

The present study was carried out in strict accordance with the Guide for the Care and Use of Laboratory Animals published by the US National Institutes of Health (NIH Publication no. 85-23, revised 1996) and was approved by the Ethics and Animal Welfare Committee of Zhengzhou University (Henan, China).

Patient consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
