**Abstract.** Matrine, one of the main alkaloid components extracted from the traditional Chinese herb, *Sophora flavescens* Ait, has various pharmacological effects, and has been reported to exert antitumor activity in melanoma. In the current study, the molecular mechanisms underlying the inhibitory effects of matrine were investigated in melanoma cell line. It was initially confirmed that matrine inhibited proliferation, invasion and induced apoptosis in human A375 and SK-MEL-2 melanoma cell lines *in vitro*. Subsequently, reverse transcription-quantitative polymerase chain reaction (RT-qPCR) analysis demonstrated that the expression of microRNA (miR)-19b-3p was significantly increased in melanoma cells and was downregulated by treatment with matrine. Furthermore, downregulated miR-19b-3p exerted effects similar to 500 µg/ml matrine on cell proliferation, invasion and apoptosis. Phosphatase and tensin homolog (PTEN) mRNA was identified as a direct target of miR-19b-3p through bioinformatics analysis and a dual-luciferase reporter assay. Additionally, western blotting and RT-qPCR analysis demonstrated that the expression of PTEN protein and mRNA were increased by the treatment with matrine. Furthermore, silencing of PTEN expression reversed the effects of matrine and miR-19b-3p downregulation in A375 and SK-MEL-2 cells. Taken together, the results indicated that matrine may suppress cell proliferation and invasion and induce cell apoptosis partially via miR-19b-3p targeting of PTEN.

## Introduction

Melanoma is a type of skin cancer caused by excessive hyperplasia of abnormal melanocytes. It is prone to relapse and metastasis, which makes it one of the leading causes of

mortality among skin cancers (1). Recently, molecular targeted therapy has provided potential for intervention at a molecular level by modulating certain signaling pathways as a form of cancer treatment and offers the promise of novel treatments for melanoma through the associated in-depth analyses of signal transduction pathways. Several antagonistic drugs directed against melanoma have been put into clinical use (2-4). However, melanoma has developed into one of the fastest growing cancers in terms of incidence rate in recent years, with an annual rate of growth of 3-5% (5,6). As a result, identifying novel targets for the treatment of melanoma remains an urgent need at this stage.

Matrine is a major alkaloid extracted from *Sophora flavescens* (7) and is also naturally present in subprostrate *Sophora* (8) and *Sophora alopecuroides* (9). Matrine exhibits several pharmacological effects, including anti-arrhythmia (10), anti-inflammation (11), and antitumor activities (12-15). The wide spread use of matrine is attributed to its low toxicity. The anticancer properties of matrine are associated with its ability to inhibit proliferation and invasion and induce apoptosis in tumor cell lines through a vast number of pathways (13,16,17). However, in the case of melanoma, the matrine mechanism of action has not been clarified.

MicroRNAs (miRNAs/miRs) are considered to have important roles in tumors. It has recently been reported that matrine alters miRNA expression profiles in SGC-7901 human gastric cancer cells, providing a novel and promising approach to identify the mechanisms of action of matrine (18). In this study, an miRNA microarray was used to screen relative miRNA levels of SGC-7901 human gastric cancer cells following matrine treatment (18). Among the results, miR-19b was of particular interest. Compared with the untreated cells, miR-19b was significantly downregulated in SGC-7901 cells following matrine treatment. Another study reported that miR-19b promoted breast cancer metastasis by targeting myosin regulatory light chain interacting protein and associated cell adhesion molecules (19). Additionally, it has been reported that miR-19b-3p may promote colon cancer proliferation and oxaliplatin-based chemoresistance by targeting SMAD4 (20). Notably, in melanoma, miR-19b was reported to be a novel upstream effector of telomerase reverse transcriptase transcription via direct targeting of mRNA encoding pituitary homeobox 1 (21). Additionally, miR-19b was downregulated following matrine treatment in gastric cancer cell lines (18).

**Key words:** melanoma, matrine, microRNA-19b-3p, phosphatase and tensin homolog, proliferation, invasion, apoptosis

Thus, in the present study, it was aimed to determine whether matrine regulates miR-19b in melanoma via certain pathways to alter the proliferation, invasion and apoptosis of melanoma cells.

## Materials and methods

**Cell lines and cell culture.** A375 and SK-MEL-2 cells have been widely used in melanoma research *in vitro* (22,23). The two cell lines were purchased from the cell bank of the Chinese Academy of Sciences (Shanghai, China). Normal human epidermal melanocytes (NHEMs) and three melanoma cell lines (SK-MEL-1, A875 and M21) were purchased from Zhong Qiao Xin Zhou Biotechnology Co., Ltd. (Shanghai, China). The cell lines were cultured in a humidified atmosphere of 5% CO<sub>2</sub>, with the temperature set to 37°C. Cells were cultured in Dulbecco's modified Eagle's medium (DMEM; Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) containing 10% fetal bovine serum (FBS; Thermo Fisher Scientific, Inc.), 100 U/ml penicillin and 100 µg/ml streptomycin.

**Reagents.** Matrine (>98% purity) was purchased from Rochem Pharma Co., Ltd. (Shanghai, China) and dissolved in DMEM medium to make a 10 mg/ml stock solution and stored at -20°C in the dark.

**Cell treatment.** A375 and SK-MEL-2 cells were exposed to different treatments and divided into several groups according to the experimental design. A375 and SK-MEL-2 cells were directly treated with 0, 250 and 500 µg/ml matrine; additionally, the two cells were transfected with anti-miR-19b-3p (cat. no. B03001; Shanghai GenePharma Co., Ltd., Shanghai, China), of miR-19b-3p mimics (cat. no. B01001) or small interfering RNA (si) targeting phosphatase and tensin homolog (PTEN; cat. no. A01001; Shanghai GenePharma Co., Ltd.) or co-transfected with si-PTEN and the first two miRNAs. In the experiments, anti-miR-control (cat. no. B04003) was used as a control for anti-miR-19b-3p mimics, miR-control (cat. no. B04001) (both from Shanghai GenePharma Co., Ltd.) was used as a control for miR-19b-3p mimics, and the blank group and scramble si-PTEN group was used as a control for si-PTEN. The blank group was untransfected cells. For transfection, A375 and SK-MEL-2 cells were cultured in the complete medium without antibiotics for >24 h and washed with 1X PBS (pH 7.4) and then transiently transfected with the appropriate constructs (20 pmol for 24-well plate or 100 pmol for 6-well plate) using Lipofectamine® 2000 (Invitrogen; Thermo Fisher Scientific, Inc.) according to the manufacturers' instructions. The sequences were as follows: Anti-miR-19b-3p, 5'-UCAGUU UUGCAUGGAUUUGCACA-3'; miR-19b-3p mimic, 5'-UGU GCAAUCCAUGCAAACUGA-3' and 5'-AGUUUUGCAU GGAUUUGCACAAG-3'; si-PTEN, 5'-AGAUGUUAGUGACA AUGAACC-3' and 5'-GGUUCAUUGUCACUAACAUCU-3'.

**Cell counting kit-8 (CCK-8) assay.** The CCK-8 assay is a method for evaluating the proliferation of A375 and SK-MEL-2 cells *in vitro*. The cells into several groups as described above. Following treatment or transfection for 24-72 h, 10 µl CCK-8 reagent was added to the medium with 90 µl DMEM and FBS.

The cells were incubated for 4 h. The absorbance at 450 nm [optical density (OD)450] was measured using a microplate reader (Bio-Rad Laboratories, Inc., Hercules, CA, USA) to estimate viable cell numbers.

**Transwell assay.** A Transwell assay was performed to analyze cell invasion. For this assay, 5x10<sup>5</sup> cells/ml A375 and SK-MEL-2 cells were cultured in the upper chamber of a 24-well Transwell Permeable Support with 100 µl serum-free DMEM; whereas, the lower chamber was filled with 400 µl medium containing 10% FBS. Subsequently, the plate was incubated for 48 h. Subsequently, cells in the upper chamber were then removed with a clean cotton swab, and cells that had migrated to the lower chamber through Matrigel were fixed with 99.5% methanol at room temperature for 30 min. To determine the number of cells via microscopy, 0.1% crystal violet staining for 10 min at room temperature was performed. Cells were counted in three randomly selected fields under an inverted light microscope and each experiment was repeated in triplicate independently.

**Flow cytometry.** In normal cells, phosphatidylserine (PS) is only distributed inside of the membrane lipid bilayer. When the earliest steps of apoptosis occur, PS translocates to the outside of the membrane, and can bind with the calcium-dependent phospholipid-binding protein Annexin V. Thus, Annexin V binding is a sensitive marker for detecting early cell apoptosis. Propidium iodide (PI) is a nucleic acid dye. It is unable to penetrate the whole cell membrane of intact cells, while it is able to penetrate and stain late apoptotic and dead cells due to the increased permeability of the cell membrane. In the current study, Annexin V-fluorescein isothiocyanate (FITC)/PI was applied to detect the apoptosis of A375 and SK-MEL-2 cells via flow cytometry according to the instructions of the FITC Annexin V Apoptosis Detection Kit I (BestBio Science, Shanghai, China). For this assay, 5x10<sup>5</sup> cells/ml were cultured following treatment of matrine for 48 h or transfection with miRs and siRNA for 24 h. A total of 1x10<sup>4</sup> cells were harvested during the flow cytometry and each experiment was performed in triplicate.

**Caspase-3/7 activity detection.** Caspase-3/7 activity detection is another method to evaluate apoptosis. According to the instructions of the Caspase-Glo® 3/7 assay (Promega Corporation, Madison, WI, USA), 4x10<sup>4</sup> of cells were seeded in 96-well plates and cultured with matrine (0, 250 and 500 µg/ml) for 24 h. Caspase-Glo® 3/7 buffer and substrate were thoroughly dissolved to form the Caspase-Glo® 3/7 reagent. The wells containing matrine, cell culture medium and Caspase-Glo® 3/7 reagent without cells were used as a blank group. The wells containing Caspase-Glo® 3/7 reagent and cells without matrine treatment in culture medium were used as negative control group. The wells containing Caspase-Glo® 3/7 reagent and cells under treatment of matrine in cell culture medium were used as the experimental groups. After incubation for 3 h at 37°C, the luminescence of each group was measured in a luminometer plate reader at an excitation wavelength of 490 nm and an emission wavelength of 530 nm.

**RNA isolation and reverse transcription-quantitative polymerase chain reaction (RT-qPCR).** Total RNA extraction from

A375 and SK-MEL-2 cells following transfection or treatment for 24 h was performed with an E.Z.N.A. Total RNA Kit I (Omega Bio-Tek, Inc., Norcross, GA, USA). RNA was reverse transcribed to cDNA using a First Strand cDNA Synthesis Kit (Thermo Fisher Scientific, Inc.) according to the manufacturer's instructions. For the detection of miR-19b-3p, RT-qPCR was performed with a high-specificity miR-19b-3p RT-qPCR Detection Kit and ABI Power SYBR Green PCR Master Mix (both from Applied Biosystems; Thermo Fisher Scientific, Inc.), with U6 small nuclear RNA used as the endogenous control for normalization. For detection of PTEN mRNA, qPCR was performed with an ABI 7500 Fast System (Applied Biosystems; Thermo Fisher Scientific, Inc.), with GAPDH for PTEN normalization used as the endogenous control. The relative expression of miR-19b-3p and PTEN mRNA were calculated using the  $2^{-\Delta\Delta C_q}$  method (21).

The primers for miR-19b-3p were as follows: RT primer, 5'-GTCGTATCCAGTGCAGGGTCCGAGGTATTCGCACTG GATACGACACACGTT-3'; forward, 5'-TCCGAAGTCAAA ACGTACCTA-3' and reverse, 5'-GTGCAGGGTCCGAGGT-3'. The primers for U6 were as follows: RT primer, 5'-GTCGTA TCCAGTGCAGGGTCCGAGGTATTCGCACTGGATACGA CAAAATA-3'; forward, 5'-TCCGATCGTGAAGCGTTC-3' and reverse, 5'-GTGCAGGGTCCGAGGT-3'. The primers for PTEN mRNA were as follows: forward, 5'-CAAGATGATGTT TGAAACTATTCCAATG-3 and reverse, 5'-5-CCTTTAGCT GGCAGACCACAA-3'. The primers for GAPDH were as follows: forward, 5'-ACAACAGCCTCAAGATCATCAGC-3' and reverse, 5'-CACGCCACAGTTTCCCGGAG-3'. The RT-PCR reaction conditions were 16°C for 10 min, 42°C for 60 min, 85°C for 5 min, and paused at 16°C. The qPCR reaction conditions were 95°C for 3 min, 40 cycles at 95°C for 30 sec and 60°C for 40 sec, melting curve (60°C for 60 sec; 95°C for 15 sec).

**Western blotting.** Total protein from A375 and SK-MEL-2 cells ( $5 \times 10^6$  cells) after transfection or treatment for 24 h was homogenized in lysis buffer and was quantified. The lysis buffer was a mix of phenylmethylsulfonyl fluoride and radioimmunoprecipitation assay buffer (Beyotime Institute of Biotechnology, Haimen, China) according to the ratio of 1:99. A bicinchoninic acid protein assay kit (Beyotime Institute of Biotechnology) was used to quantify the total protein. In the process of western blotting, the total protein (30  $\mu$ g) was separated by 10% SDS-PAGE and transferred onto a nitrocellulose membrane at 90 V for 80 min. Tris-buffered saline (TBS; 1X) and 20% Tween-20 (5 ml) were mixed to produce TBST. Following washing in 1X TBST for 3 min, the membrane was blocked in 3% FBS for 1 h at room temperature and probed with the primary antibody (mouse anti-PTEN monoclonal antibody; cat. no. BM4114; Wuhan Boster Biological Technology, Ltd., Wuhan, China) overnight at 4°C at a 1:500 dilution. Following rinsing with 1X TBST 5 times for 5 min, the membrane was probed with a secondary antibody (goat anti-mouse IgG; 1:10,000 dilution; cat. no. SA00001-1; ProteinTech Group, Inc., Chicago, IL, USA) for 2 h at room temperature. Following five washes in TBST, the films of immunoreactive products were scanned using an enhanced chemiluminescence western blot detection system (FluorChem E; ProteinSimple, San Jose, CA, USA) with the ECL Western Blotting Substrate (Thermo Fisher Scientific, Inc.). Quantified data were analyzed using

IPP 6.0 image analysis software (Media Cybernetics, Inc., Rockville, MD, USA). GAPDH (cat. no. BM3876; Wuhan Boster Biological Technology, Ltd.) served as an endogenous reference and antibody was incubated overnight at 4°C in a 1:400 dilution.

**Luciferase reporter assay.** A luciferase reporter assay was used to examine the association between miR-19b-3p and PTEN, following identification of two putative binding sites in the PTEN 3' untranslated region (UTR) using bioinformatics analysis (TargetScan; targetscan.org/vert\_72/). PCR primers were designed (forward, 5'-GTACTCGAGAGGATTAATAAA GATGGCACT-3' and reverse, 5'-ACGTCTAGAATCAATA AAGCACATGTAGGAC-3') to amplify wild-type (Wt) and mutant (Mt) PTEN 3'UTR sequences by PCR amplification, and the PUC57-Wt-PTEN 3'UTR and PUC57-Mt-PTEN 3'UTR (Sangon Biotech Co., Ltd., Shanghai, China) were used as the templates for amplification, respectively. A pmirGLO reporter vector was purchased from Promega Corporation, and the fragments that had been amplified beforehand were cloned into the multiple cloning site region of the vector to produce the recombinant vectors pmirGLO-3'UTRPTEN-Wt and pmirGLO-3'UTR PTEN-Mt.

To perform out the luciferase reporter assay, A375 cells were divided into 8 groups and cultured in two 6-well plates. pmirGLO-3'UTR PTEN-Wt or pmirGLO-3'UTR PTEN-Mt vectors (2  $\mu$ g) were co-transfected with miR-control, miR-19b-3p mimic (cat. no. B01001), anti-miR-control or anti-miR-19b-3p (cat. no. B03001) into A375 cells as described above. Luciferase activity was then determined at 24 h post-transfection with a Dual-Luciferase Assay Kit (Promega Corporation).

**Statistical analyses.** The software SPSS v.21.0 (IBM Corp., Armonk, NY, USA) was used for data analysis. The Student's t-test was used to compare between two groups. One-way analysis of variance was performed to compare data among three or more groups, and further analysis was achieved using Bonferroni or Least Significant Difference test. All values are expressed as the mean  $\pm$  standard deviation.  $P < 0.05$  was considered to indicate a statistically significant difference.

## Results

**Matrine inhibits proliferation and invasiveness, and promotes apoptosis in human A375 and SK-MEL-2 melanoma cell lines.** Matrine, one of the main alkaloid components extracted from a traditional Chinese herb, *Sophora flavescens* Ait, has wide-spread pharmacological effects. The chemical formula of matrine is  $C_{15}H_{24}N_2O$  (Fig. 1A) (24). In the current study, NHEMs, A375 and SK-MEL-2 cells were treated with various concentrations of matrine (0, 250 and 500  $\mu$ g/ml) for 0-4 days. The CCK-8 assay was used to compare the proliferation rates of cells at different matrine concentrations. The OD450 values were measured over time and the growth curves were plotted (Fig. 1B). NHEM cells treated with the increasing concentrations of matrine shared similar OD values ( $P > 0.05$ ); while A375 cells treated with 500  $\mu$ g/ml matrine exhibited significantly lower OD values than the cells treated with 250  $\mu$ g/ml matrine and 0  $\mu$ g/ml matrine ( $P < 0.05$ ).

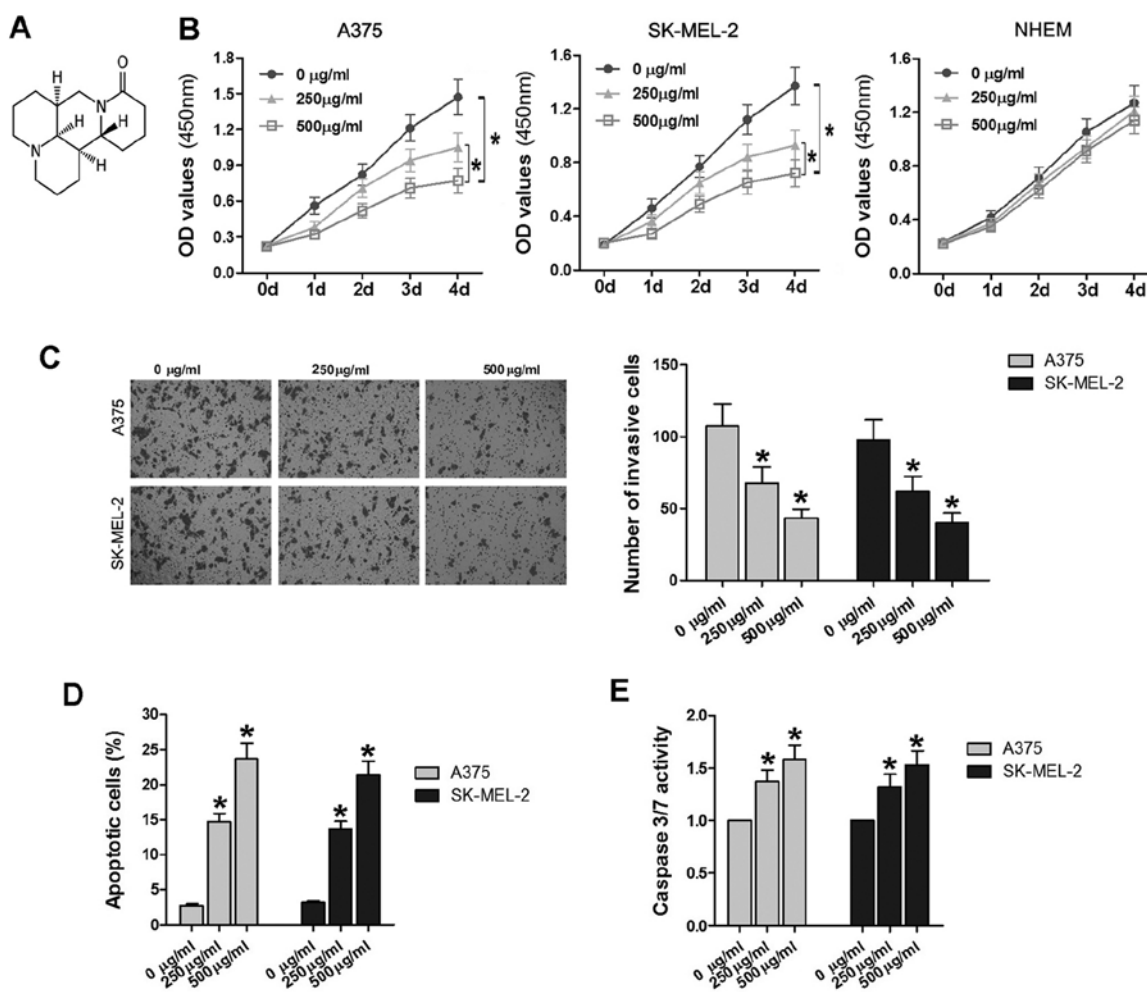

Figure 1. Matrine inhibits proliferation and invasion, and promotes apoptosis of human melanoma cell lines A375 and SK-MEL-2 *in vitro*. (A) Chemical formula of matrine. (B) Cell proliferation was determined by CCK-8 assays on NHEMs, A375 and SK-MEL-2 cells treated with 0, 250 and 500 µg/ml of matrine for 0-4 days. (C) Cell invasion was determined using Transwell assays. (D) Cell apoptosis was analyzed using Annexin/propidium iodide staining and flow cytometry and (E) caspase-3/7 activity detection was performed using A375 and SK-MEL-2 cells treated with 0, 250 and 500 µg/ml of matrine. \*P<0.05 vs. 0 µg/ml. OD, optical density; NHEM, normal human epidermal melanocytes.

Furthermore, the OD values in the 250 µg/ml group were also significantly lower than those in the 0 µg/ml group (P<0.05). A similar phenomenon was also observed in the SK-MEL-2 cell line.

Additionally, Transwell assays were performed to determine the invasiveness of following matrine treatment. After incubation for 48 h, the number of invaded A375 cells in the 250 µg/ml group (62.4±9.8) and 500 µg/ml group (43.6±6.1) was significantly decreased compared with the control group (105.3±15.7; P<0.05; Fig. 1C). Compared with the cell numbers obtained from CCK-8 assay (Fig. 1B), the relative rate of invaded cells treated in the same condition were relatively decreased, revealing that matrine could inhibit the invasiveness of A375 cells in some degree. Similarly, the number of SK-MEL-2 cells in the 250 µg/ml group (62.4±9.8) and 500 µg/ml group (60.8±7.1) was also significantly decreased compared with the control group (95.5±14.6; P<0.05; Fig. 1C).

In addition to proliferation and invasion, abnormal apoptosis is another important feature of tumor pathology (25). As demonstrated in Fig. 1D, the flow cytometry analysis revealed that when treated with 250-500 µg/ml matrine, A375 and SK-MEL-2 cells exhibited significantly increased proportions

of apoptotic cells (P<0.05); furthermore, the apoptotic rates were increased with elevated matrine concentration, suggesting that matrine induces cell apoptosis in a dose-dependent manner *in vitro*. To confirm the results, a caspase-3/7 assay was also used to detect cell apoptosis. The results demonstrated that caspase-3/7 activity was significantly increased in the 250-500 µg/ml of matrine treatment groups compared with 0 µg/ml (P<0.05; Fig. 1E), which was consistent with the findings of flow cytometry.

These findings indicated that matrine did not induce marked cytotoxicity in normal cells; and that following treatment with 250 and 500 µg/ml matrine, melanoma cells proliferation and invasion were significantly suppressed, while apoptosis was promoted, and the effects were dose-dependent.

*Matrine decreases the expression of miR-19b-3p and increases the expression of PTEN in A375 and SK-MEL-2 cells.* The aforementioned experiments demonstrated that matrine inhibited cell proliferation and invasion, and induced cell apoptosis. Subsequently, the effect of matrine on the expression of miR-19b-3p and PTEN was detected using RT-qPCR and western blot assays. miR-19b is part of the miR-17-92 and

Figure 2. Matrine increases the expression of PTEN, and decreases the expression of miR-19b-3p. (A) miR-19b-3p expression levels as determined by RT-qPCR in NHEMs, A375, SK-MEL-2, SK-MEL-1, A875 and M21 cells. \* $P < 0.05$  vs. NHEMs. (B) miR-19b-3p expression levels as detected by RT-qPCR in NHEMs, A375 and SK-MEL-2 cells treated with 0, 250 and 500  $\mu\text{g/ml}$  of matrine for 24 h. (C) PTEN protein expression levels as determined by western blot analysis in A375 and SK-MEL-2 cells treated with 0, 250 and 500  $\mu\text{g/ml}$  of matrine for 24 h. \* $P < 0.05$  vs. 0  $\mu\text{g/ml}$  or blank. RT-qPCR, reverse transcription-quantitative polymerase chain reaction; NHEM, normal human epidermal melanocytes; miR, microRNA; PTEN, phosphatase and tensin homolog.

Figure 3. miR-19b-3p targeted PTEN in A375 and SK-MEL-2 cells. (A) Putative binding sites between miR-19b-3p and PTEN 3'UTR identified through bioinformatics analysis. (B) Luciferase activity of Wt and Mt PTEN 3'UTR reporter constructs, relative to miR-control and anti-control groups, in the presence of miR-19b-3p mimic and anti-miR-19b-3p. \* $P < 0.05$  vs. respective control. (C) Expression of PTEN as detected through western blot assay in A375 and SK-MEL-2 cells transfected with miR-control, miR-19b-3p mimic, anti-miR-19b-3p or anti-miR-control. PGK, phospho-glycerate kinase promoter; Luc2, firefly luciferase; UTR, untranslated region; PTEN, phosphatase and tensin homolog; Wt, wild-type; miR, microRNA; Mt, mutant.

miR-106-363 clusters. The two miRNA clusters are in the chromosomal region 13q31.3 and Xq26.2, respectively; with miRNAs at these locations often overexpressed in cancer cells (26-28). In the current study, the expression of miR-19b-3p was measured in five types of melanoma cells, with NHEMs used as a negative control. miR-19b-3p expression in the five melanoma cell lines was upregulated compared with that

in the NHEMs ( $P < 0.05$ ; Fig. 2A). Additionally, following treatment with various concentrations of matrine for 48 h, the expression of miR-19b-3p in A375 and SK-MEL-2 cells significantly reduced in the 250-500  $\mu\text{g/ml}$  matrine groups ( $P < 0.05$ , Fig. 2B); while there was no significant difference in the expression of miR-19b-3p in NHEMs ( $P > 0.05$ ; Fig. 2B).

PTEN has been reported to be activated by matrine to induce growth inhibition and apoptosis in  $V600E$  BRAF-harboring melanoma cells (29). In the current study, PTEN protein expression was significantly increased in A375 and SK-MEL-2 cells treated with 250  $\mu\text{g/ml}$  matrine groups and 500  $\mu\text{g/ml}$  compared with the blank and 0  $\mu\text{g/ml}$  groups ( $P < 0.05$ ; Fig. 2C). Overall, matrine decreased the expression of miR-19b-3p and increased the expression of PTEN in A375 and SK-MEL-2 cells.

**miR-19b-3p targets PTEN in A375 and SK-MEL-2 cells.** The findings of the current study indicated that the expression of miR-19b-3p and PTEN was altered in matrine-treated A375 and SK-MEL-2 cells; subsequently, it was aimed to determine whether there is an association between miR-19b-3p and PTEN in melanoma cells. The bioinformatics analysis provided two interactive binding regions between miR-19b-3p and PTEN mRNA (Fig. 3A). Vast amounts of published data indicate that miRNAs can target one or more mRNA species to regulate their expression. To determine whether PTEN expression is regulated by miR-19b-3p, a dual-luciferase reporter assay was performed. During this experiment, A375 cells were divided into eight groups for the different treatments. miR-19b-3p significantly suppressed the luciferase activity in cells transfected with the pmirGLO-3'UTR PTEN-Wt; however, miR-19b-3p failed to inhibit this activity in cells containing the pmirGLO-3'UTR PTEN-Mt (Fig. 3B). Additionally, the cells were also transfected with anti-miR-19b-3p and pmirGLO-3'UTR PTEN-Wt or pmirGLO-3'UTR PTEN-Mt groups, with an anti-miR-control group as a negative control. The results revealed that luciferase activity in cells transfected with anti-miR-19b-3p and the pmirGLO-3'UTR PTEN-Wt was at its highest level compared with the other groups ( $P < 0.05$ ; Fig. 3B). Combined with the fact that the protein expression of PTEN was inhibited by miR-19b-3p overexpression and increased by miR-19b-3p downregulation (Fig. 3C), it was concluded that miR-19b-3p targeted PTEN in A375 and SK-MEL-2 cells.

Figure 4. Matrine and downregulated miR-19b-3p are able to suppress cell proliferation and invasiveness, and promote apoptosis in melanoma cells. (A) miR-19b-3p expression levels as detected by reverse transcription-quantitative polymerase chain reaction in A375 and SK-MEL-2 cells treated with 0 or 500  $\mu$ g/ml of matrine, or transfected with anti-miR-19b-3p or anti-miR-control. (B) Cell proliferation was determined by CCK-8 assays in A375 and SK-MEL-2 cells treated with 0 or 500  $\mu$ g/ml of matrine, or transfected with anti-miR-19b-3p or anti-miR-control. (C) Cell invasion was detected by Transwell assay and (D) cell apoptosis was examined using Annexin V/propidium iodide and flow cytometry in A375 and SK-MEL-2 cells treated with 0 or 500  $\mu$ g/ml of matrine, or transfected with anti-miR-19b-3p or anti-miR-control. \* $P$ <0.05 vs. 0  $\mu$ g/ml or anti-miR-control. miR, microRNA; OD, optical density.

*Matrine shares the similar effects on cell proliferation, invasiveness and apoptosis with miR-19b-3p in A375 and SK-MEL-2 cells.* miR-19b-3p was verified to be downregulated by matrine. To analyze the biological effects of matrine-mediated regulation of miR-19b-3p in melanoma, the A375 and SK-MEL-2 cell lines were treated with 0 or 500  $\mu$ g/ml matrine, or transfected with anti-miR-19b-3p or anti-miR-control. As demonstrated in Fig. 4A, the expression of miR-19b-3p was suppressed in the 500  $\mu$ g/ml matrine groups and anti-miR-19b-3p groups. Subsequently, CCK-8, Transwell assay and flow cytometry assays were performed to assess cell proliferation, invasiveness and apoptosis. Cell growth and invasion were significantly inhibited, and the number of apoptotic cells was increased in the 500  $\mu$ g/ml matrine and anti-miR-19b-3p groups compared with the control groups (Fig. 4B-D). These results indicated that matrine and downregulated miR-19b-3p suppressed cell proliferation and invasiveness, and promoted cell apoptosis. Thus, the two approaches exert similar effects on melanoma cells.

*Silencing of PTEN expression reverses the effects of matrine and miR-19b-3p in A375 and SK-MEL-2 cells.* It was attempted to determine the advanced molecular mechanisms underlying the effects of matrine and miR-19b-3p. In the current study, si-PTEN was used to silence the expression of PTEN in A375 and SK-MEL-2 cells. PTEN expression was then evaluated by western blot analysis, which demonstrated that PTEN was markedly increased following transfection with anti-miR-19b-3p or treatment with 500  $\mu$ g/ml matrine, and decreased by transfection with si-PTEN. Additionally, PTEN was reduced in cells

co-transfected with si-PTEN and anti-miR-19b-3p, and in cells treated with matrine and si-PTEN, compared with those in the anti-miR-19b-3p and matrine treatment groups, respectively ( $P$ <0.05; Fig. 5A). Transwell assay results demonstrated that compared with cells transfected with anti-miR-19b-3p or treated with 500  $\mu$ g/ml matrine alone, the number of invasive cells was significantly increased in the cells transfected with si-PTEN, co-transfected with si-PTEN and anti-miR-19b-3p, or simultaneously treated with matrine and si-PTEN ( $P$ <0.05; Fig. 5B). Flow cytometry revealed that compared with cells transfected with anti-miR-19b-3p or treated with 500  $\mu$ g/ml matrine alone, the number of apoptotic cells was significantly reduced in cells transfected with si-PTEN, co-transfected with si-PTEN and anti-miR-19b-3p, or simultaneously treated with matrine and si-PTEN ( $P$ <0.05; Fig. 5C). In these experiments, a scramble si-PTEN was used; when compared with the blank group, the scramble si-PTEN group shared a similar effect. Thus, only the blank group is shown as a negative control in Fig. 5. These results further suggested that silencing of PTEN expression reverses the effects of matrine and miR-19b-3p downregulation in A375 and SK-MEL-2 cells.

## Discussion

Due to its rapidly increasing incidence rate and poor prognosis, melanoma is one of the most lethal skin diseases. Several high-throughput studies have indicated that matrine is associated with antitumor activity in melanoma. For example, matrine has a significant inhibitory effect on the adhesion and invasiveness of malignant human A375 melanoma cell line by

Figure 5. Silencing of PTEN expression reverses the effects of matrine and miR-19b-3p in A375 and SK-MEL-2 cells. (A) PTEN expression was evaluated by western blot assay for each group of transfected A375 and SK-MEL-2 cells. (B) Cell invasion capacities determined by Transwell assay. (C) Cell apoptosis was examined using Annexin V/propidium iodide and flow cytometry. \* $P < 0.05$ . PTEN, phosphatase and tensin homolog; si, small interfering RNA; miR, microRNA.

downregulating the expression of heparanase mRNA (30); and matrine inhibits the invasiveness and metastasis of A375 cells *in vitro* (31). However, the antitumor potential and underlying mechanisms of matrine remain largely unknown.

The mechanisms may be associated with the inhibition of cellular proliferation, induction of apoptosis and autophagy, arrest of cell cycle, inhibition of angiogenesis and downregulation of target mRNA and protein expression. As reported, matrine induces cell cycle arrest and apoptosis with recovery of the expression of miR-126 in the A549 non-small cell lung cancer cell line (32). Matrine inhibited the invasion and metastasis of lung cancer cells by elevating expression of miR-133a, which further suppressed activation of epidermal growth factor receptor/protein kinase B (Akt)/matrix metalloproteinase-9 pathway (33). Furthermore, matrine can inhibit breast cancer growth via an miR-21/PTEN/Akt pathway in MCF-7 cells (34). These studies reinforce the notion that miRNAs can act as mediators of the therapeutic efficacy of natural medicines.

The current study initially confirmed the effects of matrine on cell proliferation, invasion and apoptosis in A375 and SK-MEL-2 melanoma cell lines. The results of CCK-8 assay demonstrated that the number of A375 and SK-MEL-2 cells was significantly decreased following treatment with matrine. Cell apoptosis or other factors all influence the number of living cells. In the current study, in the different groups of A375 and SK-MEL-2 cells treated with various concentrations of matrine for 48 h, live cells in the 250  $\mu$ g/ml group accounted for ~75% of the 0  $\mu$ g/ml group, live cells in 500  $\mu$ g/ml group accounted for ~60% of the 0  $\mu$ g/ml group. The results of transwell assay demonstrated that in the different groups of A375 and SK-MEL-2 cells treated with various concentrations of matrine for 48 h, invaded cells in 250  $\mu$ g/ml group accounted for ~60% of the 0  $\mu$ g/ml group, which was lower than the 75% observed in the CCK-8 assay, and invaded cells in the 500  $\mu$ g/ml group accounted for ~40% of the 0  $\mu$ g/ml group,

which was lower than the 60% observed in the CCK-8 assay. The results above verified that the decrease of cells in the invasion assay was not caused solely by reduced cell viability, but also caused by the reduced invasion capacity. Matrine has an inhibitory effect on cell invasion to a certain degree in melanoma cells. It is concluded that matrine inhibited the proliferation and invasiveness of A375 and SK-MEL-2 cells, and induced cell apoptosis with dose-dependence *in vitro*. The concentrations used in the current study were 0, 250 and 500  $\mu$ g/ml, which were similar to the concentration used in an *in vivo* experiment by Liou *et al* (35) and far beyond the effectual dose in normal cells *in vitro* (29). Next, based on the fact that miR-19b was found to be overexpressed through our previous miRNA microarray (18), miR-19b was verified to be higher in five types of melanoma cells compared with in NHEMs (36,37). Moreover, when treated with matrine, miR-19b expression was significantly downregulated in A375 and SK-MEL-2 cells, revealing that matrine could inhibit miR-19b expression *in vitro*. To explore the advanced molecular mechanisms, bioinformatics analysis was performed, which indicated the presence of two interactive binding regions between miR-19b-3p and PTEN mRNA.

The tumor inhibitor gene PTEN is a 47-kDa protein first identified as a candidate tumor suppressor gene in 1997 (38,39). Thus far, vast amounts of data published indicate that PTEN has antitumor activity. Cordes *et al* (40) reported that PTEN is associated with an aggressive tumor phenotype and with unfavorable outcome in early bladder cancer. Additionally, a high level of PTEN expression has been associated with low-grade liver metastasis and satisfactory patient survival in pancreatic cancer (41). PTEN was also reported to be activated by matrine to induce growth inhibition and apoptosis in <sup>V600E</sup>BRAF-harboring melanoma cells (29). In the current study, treatment with matrine increased the PTEN protein expression in A375 and SK-MEL-2 cells *in vitro*. Based on the results of bioinformatics analysis,

Table I. Association between PTEN gene and miR-19 in different type of cancer.

Author, year	Cancer type	miR-19 expression	PTEN expression	Function	Ref.
Liu <i>et al</i> , 2017	Wilms' tumor	Up	Down	Inhibition of miR-19b suppresses the progression of Wilms' tumor by modulating the PTEN/PI3K/Akt signaling pathway	(42)
Li <i>et al</i> , 2017	Breast cancer	Up	Down	Enhanced PTEN pseudogene 1 could inhibit breast cancer cell growth, metastasis and tumorigenicity by inhibiting miR-19b and facilitating PTEN in breast cancer	(43)
Chen <i>et al</i> , 2016	Human neuroblastoma	No description	No description	Antagomir of miR-19b decreases cell viability and phospho-Akt expression and increases PTEN expression in neuroblastoma cells	(44)

a dual-luciferase reporter assay was performed to explore the association between miR-19b-3p and PTEN. The results demonstrated that PTEN was a target of miR-19b-3p. A subsequent western blot assay demonstrated that miR-19b-3p regulated the protein level of PTEN in A375 and SK-MEL-2 cells. Numerous studies (42-48) have also reported that miR-19 (miR-19a or miR-19b) regulates the expression of PTEN, and as a result modulates cancer biology, in processes including cancer cell apoptosis, proliferation, invasion, metastasis and cell cycling (Table I). The findings of the current study demonstrated that miR-19b targets PTEN in melanoma cells; matrine also decreased the expression of miR-19b-3p and increased the expression of PTEN in A375 and SK-MEL-2 cells, while the association between matrine, miR-19b and PTEN in melanoma remained unclear. To address the biological functions of matrine and miR-19b-3p, the effects of the two components on cell proliferation, invasion and apoptosis were compared. Matrine and anit-miR-19b-3p induced similar effects in the melanoma cell lines. Furthermore, when the expression of PTEN was silenced, the inhibitory effects on proliferation and invasion and the promotion of apoptosis by matrine or downregulated miR-19b-3p were reversed.

In summary, the findings of the current study suggested that matrine suppresses cell proliferation, invasion and induce cell apoptosis partially through miR-19b-3p targeting PTEN, thus enriching the understanding of the molecular mechanisms of matrine in reducing melanoma progression and metastasis. However, the current study did not explore

whether overexpression of miR-19b-3p inhibited the effects of matrine, which requires future investigation. Additionally, determining whether matrine has potential for use *in vivo* or in a clinical setting will require thorough investigation. Various approaches, including the use of liposomes, nanoparticles, micelles and phospholipid complexes, may improve the pharmacokinetic profile of matrine, which may promote the future application of matrine in the clinic.

### Acknowledgements

Thanks are given to the People's Hospital of Jiaozuo City (Jiaozuo, China) for providing the experimental platform.

### Funding

No funding was received.

### Availability of data and materials

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

### Authors' contributions

YPW and LDZ designed the study and performed part of the statistical analysis of data. YPW, XHW, GL and JFZ performed

the cell-based experiments including CCK-8, Transwell, flow cytometry, caspase-3/7 activity detection and luciferase reporter assay. YXY and JZ were responsible for consulting the literature, involved in experimental design, bioinformatics analysis, writing the manuscript and participating in revising it critically for the comments. XLS and ZGL performed the RT-qPCR and western blot assay and performed the statistical analysis. All authors have approved the final manuscript.
