DOI: 10.3892/ijo.2020.5083

Abstract. Although it has been previously documented that a hypoxic environment can promote glycolysis and the malignant progression of oral squamous cell carcinoma (OSCC) cells, the specific underlying mechanism remains unclear. Phosphoglycerate kinase 1 (PGK1) has been previously reported to serve an important role in tumor metabolism. The aim of the present study was to investigate the effects of hypoxia and PGK1 on glycolysis, stem cell-like properties and epithelial-mesenchymal transition (EMT) in OSCC cells. Cell Counting Kit-8 assays were performed to examine tumor cell viability under hypoxic conditions. Sphere formation, immunohistochemistry, western blotting, Transwell assays and mouse xenograft studies were performed to assess the biological effects of PGK1. Under hypoxic conditions, phosphoglycerate PGK1 expression was found to be upregulated, which resulted in the potentiation of stem cell-like properties and enhancement of EMT. However, PGK1 knockdown reversed hypoxia-mediated glycolysis, stem cell-like properties, EMT in addition to inhibiting OSCC cell invasion and migration. PGK1 knockdown also inhibited tumour growth, whilst the overexpression of PGK1 was demonstrated to promote tumour growth in mouse xenograft models *in vivo*. Downstream, activation of the AKT signalling pathway reversed the series of changes induced by PGK1 knockdown. PGK1 expression was found to be upregulated in human OSCC tissues, which was associated with the pathological differentiation of tumours and lymph node metastasis. To conclude, results from the present

study demonstrate that hypoxia can increase PGK1 expression, resulting in the promotion of glycolysis, enhancing stem cell-like properties and EMT by activating AKT signalling in OSCC.

Introduction

Oral squamous cell carcinoma (OSCC) is the most prevalent malignant tumour in the oral and maxillofacial region (1). The high incidence of oral cancer is attributed to physical, chemical and biological factors. According to the statistics of American Cancer Association, there were about 48,000 newly diagnosed cases of OSCC in 2016, which accounted for 3% of all new malignant tumor cases (2-5). At present, surgery combined with radiotherapy and chemotherapy is the primary treatment option for oral cancer. However, the 5-year survival rate of patients with oral cancer has not significantly improved over the past decade (6,7). The invasive and metastatic ability of tumour cells is one of the main factors affecting the prognosis of patients (8). The growth of tumours is influenced by the surrounding microenvironment (9). However, the molecular mechanism underlying the rapid tumour growth, maintenance of invasiveness and metastatic capability remain unclear.

Epithelial-mesenchymal transformation (EMT) refers to the biological process in which epithelial cells transform into cells that exhibit a more mesenchymal phenotype. It has been previously reported to serve an important role in embryonic development, wound healing and tumour metastasis (10-14). The main characteristic of EMT is a reduction in the expression of cell adhesion molecules such as E-cadherin and the conversion of expression profiles from keratin to vimentin in the cytoskeleton (10). It is an important biological process for the invasion and migration of OSCC cells. The regulation of EMT involves a complex network of signalling pathways, including those of the transforming growth factor- β family, Wnt, Notch, epidermal growth factor (EGF), hepatocyte growth factor, fibroblast growth factor (FGF) and hypoxia-inducible factor (HIF) (15-17). Malignant tumour cells mainly meet their metabolic demands through glycolysis, even under a plentiful supply of oxygen, in a phenomenon known as the Warburg effect (18). Glycolysis has

Key words: hypoxia, phosphoglycerate kinase 1, epithelial-mesenchymal transition, stem cell-like properties, oral squamous cell carcinoma

been previously demonstrated to promote the invasion of HeLa cells (19). A number of transcription factors, including HIF-1 α , c-Myc, NF- κ B and p53, have been previously found to be involved in the regulation of glycolysis in cancer cells (20-23). In OSCC, pyruvate kinase M1/2 dephosphorylation has been previously demonstrated to promote the Warburg effect and tumorigenesis, whilst silencing phosphofructokinase, platelet (PFKP) expression inhibited starvation-induced autophagy, glycolysis and EMT (24).

PGK participates in the second stage of glycolysis, where it catalyzes the conversion of 1,3-diphosphoglyceride into 3-phosphoglycerate, consuming a molecule of ADP and produces a molecule of ATP (25). Phosphoglycerate kinase (PGK) is an essential enzyme that is associated with the survival of every organism, where mutations in PGK results in a number of metabolic disorders, including mental retardation, neurological disorders and rhabdomyolysis (25). There are PGK two main subtypes of PGK, namely PGK1 and PGK2, both of which have similar functions and structures (26). PGK1 serves a speed limiting role in the second stage of glycolysis during the regulation of energy production and redox balance (27). Aberrant PGK1 expression has been previously associated with the occurrence of a number of diseases, including Parkinson's disease and hereditary non-spherical hemolytic anemia (28-30). By contrast, the PGK2 gene is only expressed in spermatogenic cells, where its only known function is to compensate for the inhibition of PGK1 expression caused by the inactivation of X chromosomes in spermatocytes (31). Since PGK1 is a mediator of glycolysis that supplies ATP for tumor cell metabolism under hypoxic conditions, it has been reported to participate in the development and progression of numerous cancer types, including renal, gastric and lung cancer (32-34).

In the present study, hypoxia-induced glycolysis was established in OSCC tumour cell lines *in vitro*, where the effects of PGK1 on the invasive and migratory capabilities of OSCC cells and the underlying molecular mechanism were investigated. Results from the present study demonstrated that hypoxia resulted in the activation of PGK1, in turn promoting glycolysis, increasing stem cell-like properties and promoting EMT via AKT signalling in OSCC.

Materials and methods

Patients and tissue samples. In total, 92 OSCC tissue samples and 20 matched non-cancerous tissue samples were collected from the inpatients (age range, 34-87 years; sex 58 males and 34 females) at the Affiliated Stomatological Hospital of Sun Yat-sen University (Guangzhou, China) from June 2008 to June 2017. Immunohistochemical assays for PGK1 were performed on all 112 samples. The removal of tissue samples from patients was approved by the ethical review committee of the Affiliated Stomatological Hospital of Sun Yat-sen University.

All patients received radical surgery and none received any form of pre-surgical adjuvant therapy. The clinical and pathological characteristics (sex, age, differentiation, T stage, clinical stage and lymph node metastasis) of the cancer in each patient were established in accordance with the criteria of the American Joint Committee on Cancer (35). The experiments

were performed with the understanding and written consent of each subject. The study methodologies conformed to the standards set by the Declaration of Helsinki.

Antibodies. Anti-PGK1 (cat. no. ab38007), anti-SRY-box transcription factor 2 (Sox2; cat. no. ab93689), anti-octamer-binding transcription factor 4 (Oct4; cat. no. ab181557), anti-Nanog (cat. no. ab106465), anti-phosphorylated (p)-AKT (cat. no. ab38449) and anti-AKT (cat. no. ab8805) were purchased from Abcam (Abcam). Anti-HIF-1 α (cat. no. 36169), anti-E-cadherin (cat. no. 3195), anti-vimentin (cat. no. 5741), anti-Slug (cat. no. 9585) and anti- β -actin (cat. no. 8457) primary antibodies were purchased from Cell Signalling Technology, Inc.

Cell lines and treatment. The cell lines HSC3 and HN6 were obtained from the American Type Culture Collection. Cells were cultured in DMEM medium (Gibco; Thermo Fisher Scientific, Inc.) supplemented with 10% FBS (Hyclone; GE Healthcare Life Sciences) in 5% CO₂ at 37°C under normoxic conditions, where the medium was replaced every day. For hypoxia treatment, cells were incubated in 1% O₂, 5% CO₂ at 37°C for 12 h or 24 h followed by returning to normoxic conditions for subsequent experimentation. The AKT activator SC79 (cat. no. HY-18749; MedChemExpress) was dissolved in DMSO to a stock concentration of 10 mM, where a final concentration of 10 μ M was used at 37°C for 24 h under normoxic conditions.

RNA interference and lentiviral transfection. PGK1 and control siRNA were used in this study, which were synthesised by Guangzhou RiboBio Co., Ltd. After diluting Lipofectamine[®] RNAiMAX (Invitrogen; Thermo Fisher Scientific, Inc.) and PGK1 or control siRNA with Opti-MEM (Invitrogen; Thermo Fisher Scientific, Inc.), they were mixed and incubated at room temperature for 5 min. PGK1 siRNA (50 nM) was then introduced into HSC3 and HN6 cells for 12 h before treatment according to the manufacturer's protocols. Sequences of the three PGK1 siRNAs were as follows: PGK1 si-1, 5'-CCAAGT CGGTAGTCCTTAT-3'; PGK1 si-2 5'-GCTTCCGAGCT TCACTTT-3'; PGK1 si-3 5'-TGTCAGTCTGACAAGTTT-3'. The negative control duplex used (cat. no. siN0000001-1-5), which was also provided by Guangzhou RiboBio Co., Ltd., was not homologous to any mammalian genes.

Lentiviral plasmid pLVX-mCMV-ZsGREEN-Puro was constructed to overexpress PGK1 whereas the lentiviral plasmid pLVX-shRNA-tdTomato-Puro was constructed to knock down PGK1 expression in HSC3 cells. The multiplicity of infection of both PGK1 knockdown and overexpression was 10. The sequence ligated into the lentiviral plasmid to knock down PGK1 was as follows: 5'-CTGACAAGTTTGTATGA GAATGCTCGAGCATTCTCACTCAAACTTGTCAGTTT TT-3'. The lentivirus packaging process was completed by Guangzhou MingKong Co., Ltd. The recombinant virus plasmid encoding lentivirus particles and its three auxiliary packaging vector plasmids (pGag/Pol, pRev, pVSV-G) were prepared and transfected into 293T cells with Lipofectamine[®] 2000 (Invitrogen; Thermo Fisher Scientific, Inc.). The concentration of all of the plasmids used per transfection reaction into 293T cells was 300 ng/ μ l.

Cell viability assay. HSC3 and HN6 cells from the control and hypoxia groups were seeded at 1,000 per well in 96-well plates and cultured for 0, 24, 48 and 72 h at 37°C. Cell viability was measured using a Cell Counting Kit-8 kit assay (CCK-8; Dojindo Molecular Technologies, Inc.). After adding 10 μ l CCK-8 reagent per well, plates were incubated at 37°C for 1 h. Absorbance in each well was measured at 450 nm using a microplate reader (Bio-Rad Laboratories, Inc.) according to the manufacturer protocols.

Immunohistochemistry. The tissues obtained were first fixed in 4% paraformaldehyde for 24 h at room temperature and embedded in paraffin to immobilise the tissues, following which immunohistochemical staining of 3- μ m thick paraffin sections was subsequently performed. The tissue sections were first deparaffinized with xylene and rehydrated with a descending ethanol gradient before being boiled in a pressure cooker with sodium citrate buffer at 99°C for 20 min for antigen retrieval. Endogenous peroxidase/phosphatase activities within the sections were then quenched at room temperature for 10 min using 3% hydrogen peroxide, followed by blocking in 5% goat serum (Wuhan Boster Biological Technology, Ltd.) at room temperature for 30 min. The sections were then incubated with the respective PGK1, E-cadherin, Vimentin, Slug, Sox2, Oct4 and Nanog primary antibodies (1:250 dilution) overnight at 4°C, following which they were incubated with horseradish-peroxidase (HRP)-conjugated secondary antibodies (1:200; cat. no. 7074s; Cell Signaling Technology, Inc.) diluted in 1% BSA (Wuhan Boster Biological Technology, Ltd.) at room temperature for 30 min. For color development, 3,3'-diaminobenzidine was used. An Axio Imager Z2 light microscope (magnifications, x100 and x400; Zeiss AG) was used for image acquisition. Immunohistochemical staining was assessed in terms of staining intensity and the proportion of positively staining cells using Image-Pro Plus 6.0 software (Media Cybernetics, Inc.). The scoring system for staining intensity was as follows: i) 0, no staining; ii) 1, weak staining; iii) 2, medium staining; and iv) 3, strong staining. The scoring system for the proportion of positive cells was determined as follows: i) 0, 0%; ii) 1, 25%; iii) 2, 50%; iv) 3, 75%; and v) 4, 100%. These two scores were then multiplied together to give the final score, where a score >4 was classified as high expression whereas a score \leq 4 was classified as low expression.

Western blot analysis. Cells were collected and treated at 4°C for 30 min with RIPA lysis buffers (Thermo Fisher Scientific, Inc.) supplemented with protease inhibitors and phosphatase inhibitors (Thermo Fisher Scientific, Inc.). Cell lysates were collected and centrifuged at 4°C for 30 min at 14,000 x g. The supernatant was collected and protein concentration was determined using a bicinchoninic acid protein assay kit (CoWin Biosciences). Total protein (25 μ g) was subsequently separated by 10% SDS-PAGE and transferred onto a polyvinylidene fluoride membrane (EMD Millipore) with 10% SDS-PAGE. After blocking with 10% BSA (CoWin Biosciences) at room temperature for 1 h, the membranes were incubated with HIF-1 α , PGK1, E-cadherin, Vimentin, Slug, Sox2, Oct4, Nanog, p-AKT, AKT or β -actin primary antibodies (1:1,000 dilution) overnight at 4°C, followed by incubation with a HRP-conjugated

secondary antibody (1:2,000 dilution; cat. no. 7074s; Cell Signaling Technology, Inc.) at room temperature for 1 h. An enhanced chemiluminescence kit (Cell Signaling Technology, Inc.) and the ImageQuant Las4000mini system (GE Healthcare Life Sciences) were used to visualize the bands. β -actin was used as an internal control. The signal intensities were quantified using ImageJ version 1.48u software (National Institutes of Health)

Glucose consumption and lactate production analysis. Cells were seeded into 6-well plates at the same density of 2.5×10^5 cells per well and cultured under hypoxic conditions for 12 h followed by incubation under normoxic conditions for 12 h after siRNA transfection. The cell culture supernatants were obtained from each treatment group, where glucose consumption and lactic acid production were measured. Glucose consumption was measured at 37°C for 15 min using glucose detection kits (cat. no. F006-1-1; Nanjing Jiancheng Bioengineering Institute) and lactic acid production was measured at 37°C for 5 min using lactic acid detection kits (cat. no. A019-2-1; Nanjing Jiancheng Bioengineering Institute) in accordance with the manufacturer's protocol.

Sphere formation. The sphere formation assays were performed in ultra-low attachment 24-well plates (Corning, Inc.). A total of 1,000 cells were seeded into each well, where DMEM containing 2% B27 (Invitrogen; Thermo Fisher Scientific, Inc.), 20 ng/ml basic fibroblast growth factor (bFGF; Invitrogen; Thermo Fisher Scientific, Inc.) and 20 ng/ml epidermal growth factor (EGF; Invitrogen; Thermo Fisher Scientific, Inc.) were added. The experimental group received hypoxia treatment (1% O₂, 5% CO₂) at 37°C for 12 h, whilst control cells were incubated in normoxic (95% air/5% CO₂) conditions without hypoxia treatment. Both treatment groups were then incubated under normoxic (95% air/5% CO₂) conditions at 37°C for 14 days. The resulting parameters of sphere formation, including the diameter of spheres and the number of spheres per 1,000 cells, were observed using an Axio Imager Z2 light microscope (magnification, x100; Carl Zeiss AG).

Migration and invasion assay. For cell migration, 4×10^4 cells were seeded into the upper chamber of Transwell assay plates (24-well insert; pore size, 8 μ m; BD Biosciences) suspended in serum-free medium 12 h following normoxic or hypoxic treatment. The lower chamber was filled with DMEM supplemented with 10% FBS. For cell invasion, Matrigel (Corning, Inc.) was added into the upper chambers at 37°C for 1 h in accordance with the manufacturer's protocols, following which 8×10^4 cells were seeded into the upper chambers with Matrigel-coated membranes 12 h following normoxic or hypoxic treatment. The Transwell chambers were then incubated at 37°C under normoxic conditions (5% CO₂ atmosphere) for 36 h. After incubation, Transwell membranes was fixed with 4% paraformaldehyde at room temperature for 30 min, stained with 0.1% crystal violet at room temperature for 20 min and observed under the Axio Imager Z2 light microscope (magnification, x100; Carl Zeiss AG). The number of migrated and invaded cells was then counted in five randomly selected fields per chamber.

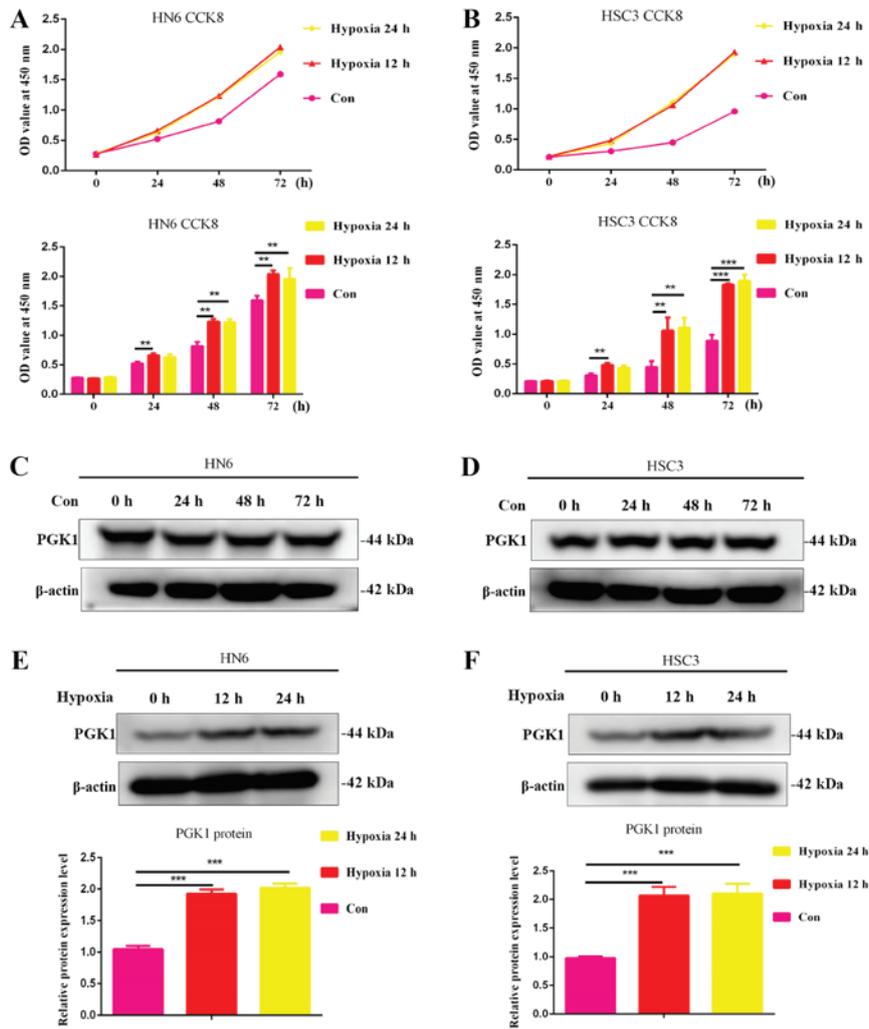

Figure 1. Hypoxia increases oral cancer cell viability and promotes the expression of PGK1. (A) HN6 and (B) HSC3 cells were cultured under hypoxic conditions for 0, 6, 12, 18 and 24 h, following which cell viability was measured using CCK-8 assays. Western blotting was used to measure changes in PGK1 expression in (C) HN6 and (D) HSC3 cells after normal culture conditions for 0, 24, 48 and 72 h. Western blotting was used to measure changes in PGK1 expression in (E) HN6 and (F) HSC3 cells following 12 and 24 h culturing under hypoxic conditions. ** $P < 0.01$ and *** $P < 0.001$, $n = 3$. Con, control. PGK1, phosphoglycerate kinase 1; OD, optical density; CCK8, Cell Counting Kit-8.

Tumorigenesis in nude mice. A total of 20 female SCID mice (age, 4-6 weeks; weight, 20-25 g) were purchased from the Laboratory Animal Center of Sun Yat-sen University (Guangzhou, China) and maintained under pathogen-free conditions. The temperature of feeding environment is controlled at 18-26°C under normoxic conditions, the relative humidity is 40-70% and 12-h light/dark cycle. All mice had free access to food and water. SCID mice were randomly divided into the following four groups ($n = 5$ in each group): i) Overexpression control (Vector); ii) overexpression (PGK1); iii) knockdown control group (shVector); and iv) knockdown (shPGK1). HSC3 cells were digested by trypsin for 3 min, neutralized with 10% FBS medium and collected by centrifugation. Then, HSC3 cells (1×10^6) were diluted in 200 μ l sterile PBS and injected into the unilateral abdominal region adjacent to the axilla of the hind limbs using a 1 ml syringe. Tumour volume was measured weekly (tumour volume = length x width x width) / 2) and all mice were euthanized after 1 month after cell injection and the final tumor measurement, following which the tumour mass was measured. Tissue specimens were fixed with 4% paraformaldehyde at room temperature for 24 h

and embedded for subsequent immunohistochemical staining. This present animal study was approved by the Experimental Animal Ethics Committee of Sun Yat-sen University (Guangzhou, China). The animal experiment lasted for 2 months. Any mice that were found to be slow growing, not eating or infected by skin ulceration caused by mutual fights were euthanized by cervical dislocation. After the tumor cells are implanted into the mice, if any of the mice were observed to suffer from anorexia, inability to eat normally, significant weight loss and other abnormalities, the nutrition (melon seeds, wheat) will be enhanced immediately. Euthanasia would be performed in case of rapid weight loss of >20%, weakness, loss of appetite, inability to drink or eat, skin ulceration and infection caused by fighting with each other. Animal health and behaviour were monitored every day and no animal was found dead during the present study. A combination of criteria was used for confirming death, including the lack of pulse or breathing and rigor mortis.

TCGA Data Collection and Processing. The gene expression RNAseq and clinical data of 566 cases of the head and neck

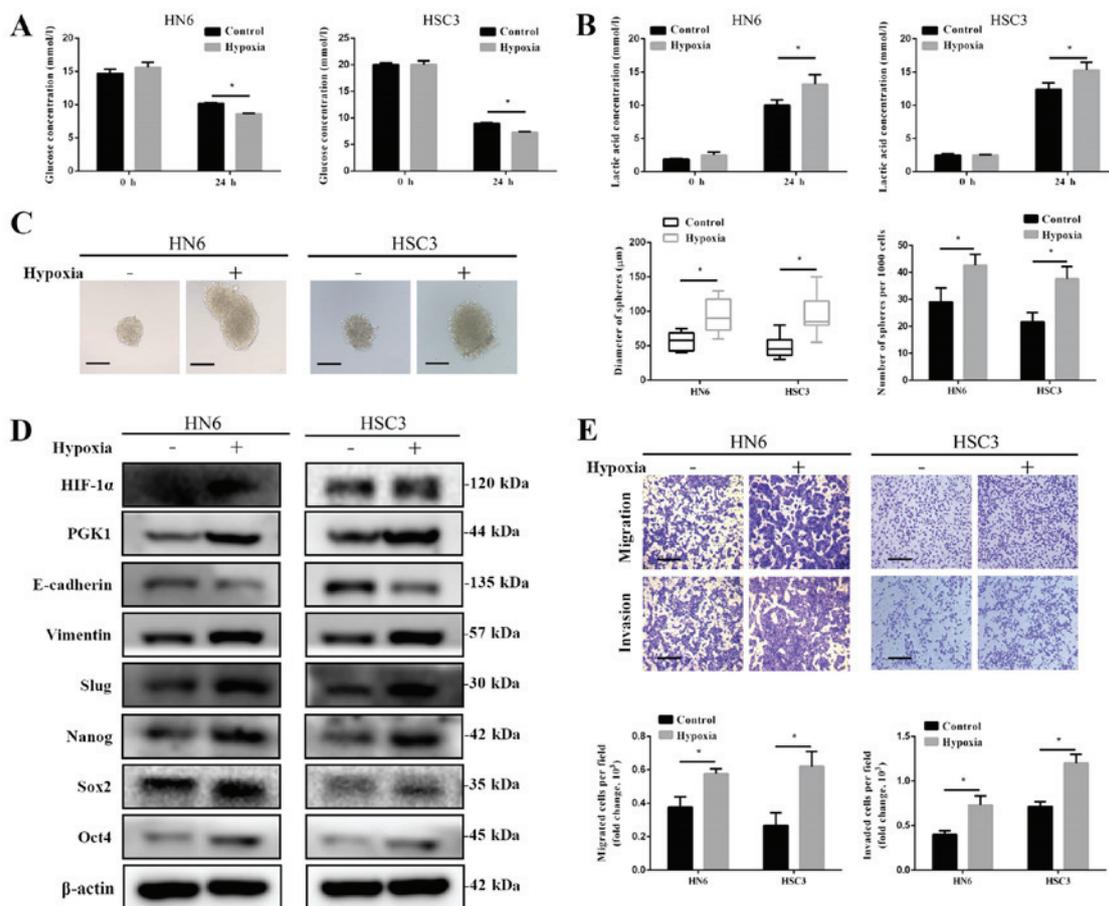

Figure 2. Effects of hypoxia on glycolysis, stem-like properties, migration and invasion of oral squamous cell carcinoma cells. (A) Glucose and (B) lactic acid levels in the culture supernatant of HN6 and HSC3 cells were measured after culturing under hypoxic conditions. (C) Both diameters and numbers of spheres formed by HN6 and HSC3 cells were increased following culturing under hypoxic conditions. Scale bar, 50 μ m. (D) Hypoxic treatment in HN6 and HSC3 cells upregulated the expression PGK1, Sox2, Oct4, Nanog, Vimentin and Slug proteins, whilst reducing the expression of E-cadherin. squamous cell carcinoma dataset (566 cases) were downloaded from The Cancer Genome Atlas (TCGA) using the UCSC Xena browser (<https://xenabrowser.net>) (36). In these cases, the primary tumors from the oral cavity (oral cavity, oral tongue, floor of mouth, alveolar ridge, hard palate and buccal mucosa) included 284 oral squamous cell carcinoma specimens and 30 normal oral epithelial tissue samples. The gene expression data and survival results of were analysed using the R software (R version 3.5.3; <http://bioconductor.org/biocLite.R>) and related R packages, including 'dplyr', 'tidyr', 'ggplot2', and 'survminer' R packages (37-40).

Statistical analysis. Unpaired t-test was used to compare two groups of data and one-way ANOVA followed by Tukey's test was used for multiple comparisons using SPSS version 19.0 (IBM Corp.). P <0.05 was considered to indicate a statistically significant difference. χ^2 test was used to evaluate the association between PGK1 expression and the clinicopathological characteristics of patients with OSCC. Wilcoxon signed rank test was used to compare the immunostaining scores between adjacent noncancerous tissue (ANCT) and OSCC. Kruskal-Wallis test followed by Dunn's test was used to compare the immunostaining scores among the OSCC tissues at different stages of differentiation. U Mann-Whitney

test was used to compare the immunostaining scores between OSCC tissue specimens with or without lymph node metastasis. The Kaplan-Meier method and log-rank test were used to compare the overall survival of patient. Data were presented as mean \pm SD. Each experiment was performed \leq 3 times.

Results

Hypoxia promotes the proliferation of OSCC cells and increases the expression of PGK1. Oral cancer cell lines HSC3 and HN6 were cultured under hypoxic conditions for 0, 12 and 24 h, where the results showed that hypoxia for 12 and 24 h significantly increased cell viability in both oral cancer cell lines (Fig. 1A and B). These findings suggest that hypoxic conditions at appropriate time periods can promote the growth of OSCC cells. There were no significant changes in PGK1 expression in HN6 and HSC3 cells under normal culture conditions at any of the timepoints tested (Fig. 1C and D). In addition, PGK1 expression in HN6 and HSC cells was measured following hypoxia treatment. The results showed that the expression of PGK1 was significantly upregulated 12 and 24 h following culture under hypoxic conditions (Fig. 1E and F).

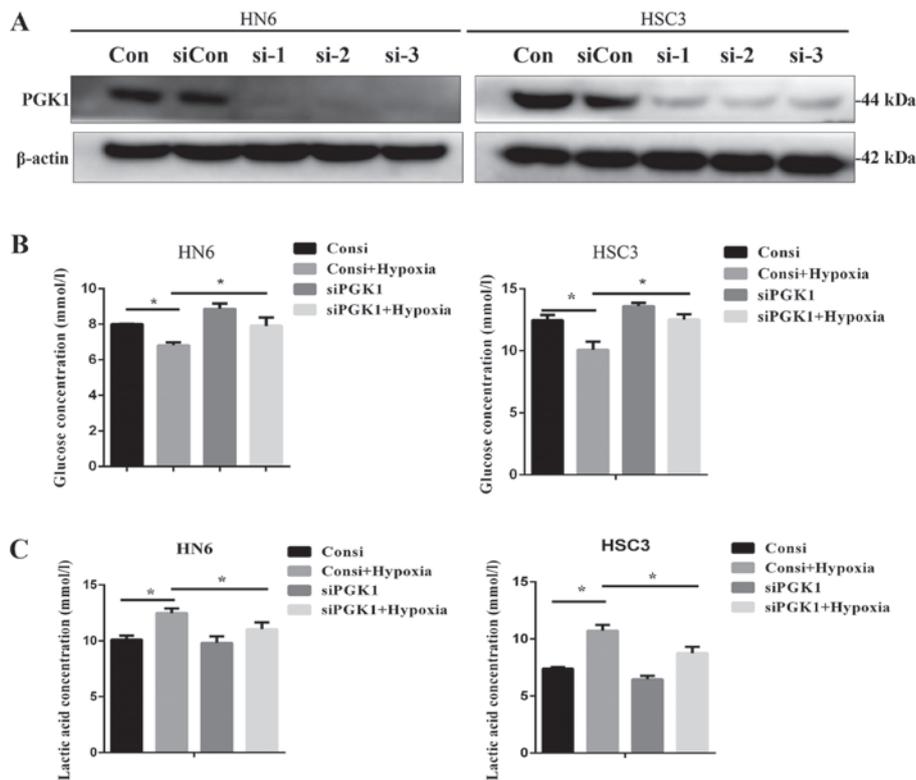

Figure 3. Knockdown of PGK1 expression reverses hypoxia-induced glycolysis. (A) Western blotting was used to measure PGK1 expression in HN6 and HSC3 cells after PGK1 knockdown. Knockdown of PGK1 expression partially reversed the (B) increase in glucose consumption and (C) lactic acid production under hypoxic conditions. * $P < 0.05$, $n = 3$. PGK1, phosphoglycerate kinase 1; si, small interfering RNA; ConsiRNA, control siRNA.

Hypoxia promotes glycolysis, increases stem cell-like properties and enhances OSCC cells migration and invasion. To investigate the effect of hypoxia on the glucose metabolism of OSCC cells, HN6 and HSC3 were cultured under hypoxic conditions for 12 h followed by incubation under normoxic conditions for 12 h. Glucose consumption and lactic acid production were found to be significantly higher in cells cultured under hypoxic conditions compared with cells cultured under normoxic conditions (Fig. 2A and B). These findings suggest that hypoxia may promote glycolysis in OSCC cells. The effects of hypoxia on OSCC cell invasion and migration, in addition to the expression of stem cell markers, were subsequently examined. It was found that the diameter and number of spheroids formed were significantly higher in cells incubated under hypoxic conditions compared with cells cultured under normoxic conditions (Fig. 2C). Hypoxia treatment was also revealed to upregulate the expression of stem cell markers Sox2, Oct4 and Nanog in HN6 and HSC3 cells (Fig. 2D). In addition, the expression levels of PGK1, in addition to those of vimentin and slug, were found to be upregulated following culture under hypoxic conditions compared with cells cultured under normoxic conditions (Fig. 2D). By contrast, E-cadherin expression was revealed to be lower compared with that in normoxic cells (Fig. 2D). Since EMT is a key process in potentiating tumour migration and invasion (7), the role of hypoxia in the invasion and migration of OSCC cells was assessed by Transwell assays. Hypoxia was found to significantly enhance HN6 and HSC3 cell migration and invasion compared with normoxic cells (Fig. 2E).

PGK1 knockdown reverses the effects of hypoxia on glucose consumption, stem cell-like characteristics and EMT in OSCC cells. To study the effect of hypoxia treatment on OSCC cells after PGK1 knockdown, the effect of siRNA transfection on the PGK1 expression under normoxic conditions was first verified by western blotting (Fig. 3A). PGK1 knockdown using PGK si-01 was found to partially but significantly reverse the positive effects of hypoxia on glucose consumption (Fig. 3B) and lactic acid production (Fig. 3C). In terms of EMT, PGK1 knockdown markedly reversed the increases in the expression of EMT markers vimentin and Slug whilst markedly preventing the reduction in E-cadherin caused by hypoxia (Fig. 4A). PGK1 knockdown did not significantly affect HIF-1 α expression, which was upregulated by hypoxia (Fig. 4A). PGK1 knockdown was found to markedly suppress the expression of stem cell markers Sox2, Oct4 and Nanog in addition to reversing the hypoxia-induced upregulation of these stem cell markers (Fig. 4A). Under hypoxic conditions, silencing PGK1 expression also significantly inhibited cell migration and invasion (Fig. 4A and C), whilst also significantly reducing the diameter and number of spheres formed by HN6 and HSC3 cells compared with those transfected with control siRNA (Fig. 4A and B).

PGK1 knockdown inhibits tumour growth whereas the upregulation of PGK1 expression promotes tumour growth in vivo. To study the effect of PGK1 on the phenotype of OSCC tumours *in vivo*, pre-constructed HSC3 PGK1 knockout (shPGK1) or overexpression cell lines were injected into the subcutaneous tissues of SCID mice. Tumour volumes and weights were

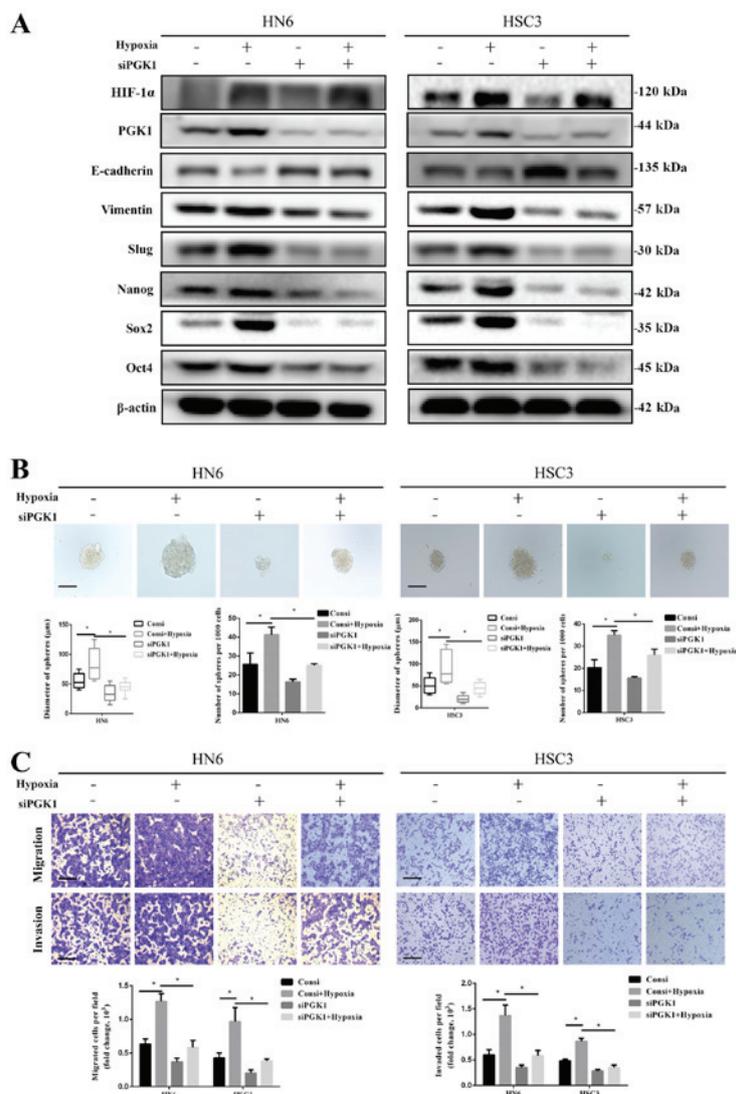

Figure 4. Knockdown of PGK1 expression reverses hypoxia-activated stem-like properties and epithelial-mesenchymal transition in oral squamous cell carcinoma cells. (A) HN6 and HSC3 cells were treated under hypoxic conditions and/or transfected with siPGK1, following which the expression of the indicated proteins was measured by western blotting. (B) Sizes and numbers of spheroids formed were measured after HN6 and HSC3 cells were cultured under hypoxic conditions and/or transfected with siPGK1. Spheroids with diameters >50 μ m were displayed. Scale bar, 50 μ m. (C) Transwell assays were used to measure HN6 and HSC3 cell migration and invasion following culturing under hypoxic conditions and/or transfection with siPGK1. * P <0.05, n=3. Scale bar, 50 μ m. found to be significantly reduced in the group injected with cells transfected shPGK1 with compared with those injected with cells transfected with the shVector 1 month after injection (Fig. 5A). By contrast, tumour volumes and weights were demonstrated to be significantly increased in the group transfected with cells overexpressing PGK1 compared with those injected with cells transfected with the vector (Fig. 5A). Furthermore, compared with those in the PGK1 overexpression group, mice in the shPGK1 group also exhibited markedly lower levels of PGK1, vimentin, Slug, Sox2, Oct4 and Nanog expression, whilst showing higher levels of E-cadherin expression (Fig. 5B and C).

PGK1 promotes stem cell-like properties and EMT in OSCC cells through the AKT signalling pathway. The activity of the AKT signalling pathway was next measured in OSCC cells under normoxic conditions. PGK1 knockdown was

found to reduce p-AKT phosphorylation (Fig. 6A). SC79, an activator of AKT, was used to investigate the effects of the AKT signalling pathway on PGK1-mediated stemness and EMT in OSCC cells, also under normoxic conditions. SC79 treatment was revealed to increase AKT phosphorylation whilst reversing the inhibitory effects of PGK1 knockdown on vimentin, Slug, Sox2, Oct4 and Nanog expression (Fig. 6B). In addition, increases in E-cadherin expression induced by PGK1 knockdown was also found to be reversed by SC79 treatment (Fig. 6B). SC79 was found to promote significantly potentiate sphere formation, migration and invasion in HN6 and HSC3 cells following PGK1 knockdown (Fig. 6C and D). These findings suggest that PGK1 may promote OSCC stemness and EMT by activating the AKT signalling pathway.

PGK1 expression is correlated with clinicopathological features in patients with OSCC. To clarify if the levels of PGK1

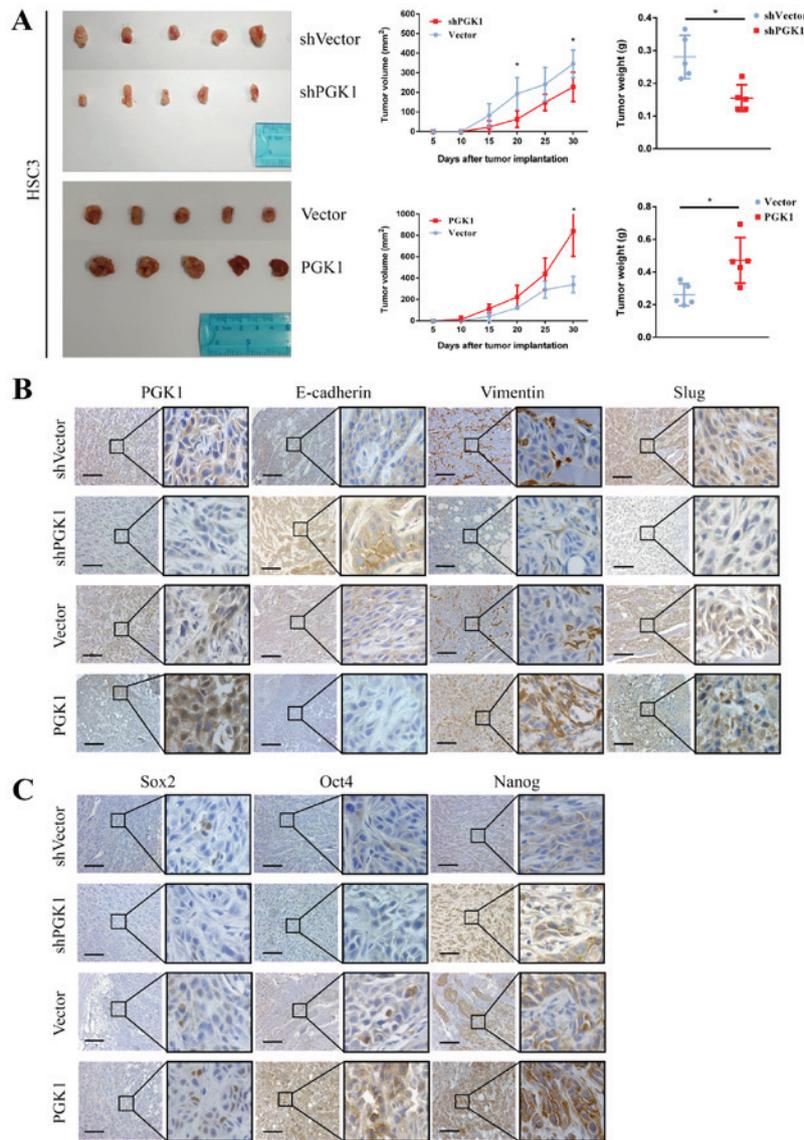

Figure 5. PGK1 knockdown inhibits tumour growth whereas the PGK1 upregulation promotes tumour growth *in vivo*. (A) Images of the tumours isolated from mice in the shVector, shPGK1 and Vector and PGK1 groups. Volume of the tumours over 30 days, in addition to the weight of the tumours following euthanasia, were measured. Representative IHC images showing the staining of (B) epithelial-mesenchymal transition and (C) stem cell markers in the tumour xenografts isolated from each of the four groups. * $P < 0.05$, $n = 5$. expression is associated with the clinicopathological characteristics of patients with OSCC, PGK1 expression was measured in tissue samples obtained from 92 patients with OSCC and 20 ANCT specimens by immunohistochemistry (Fig. 7A). Semi-quantitative analysis showed that the PGK1 expression in OSCC specimens was significantly higher compared with that in ANCT (Fig. 7B). Compared with that in well-differentiated OSCC tissue samples, PGK1 expression was found to be significantly higher in moderately and poorly differentiated OSCC tissues (Fig. 7C). PGK1 expression was also demonstrated to be significantly higher in OSCC tissue specimens with lymph node metastasis compared with that in OSCC specimens without lymph node metastasis (Fig. 7D). The relationship between PGK1 expression and the clinicopathological characteristics of patients with OSCC was next examined. PGK1 expression was found to significantly associate with tumour differentiation, clinical staging and lymph node metastasis, but not with age, sex or T stage (Table I).

PGK1 expression levels in patients with OSCC patients is associated with survival and prognosis. The levels of PGK1 expression was next compared between 284 OSCC samples and 30 normal oral mucosal epithelial tissue samples obtained from the TCGA database. PGK1 expression was revealed to be significantly upregulated in OSCC samples compared with that in the normal oral mucosal epithelial tissue samples (Fig. 8A). Survival analysis showed that the overall survival rate of patients with high expression of PGK1 was significantly reduced compared with those with low PGK1 expression (Fig. 8B).

Discussion

Strong invasive and migratory capacities are among the main causes underlying oral cancer cell metastasis, which is particularly prone to metastasizing to cervical lymph nodes and distant organs, significantly reducing the quality of life of patients (41-43).

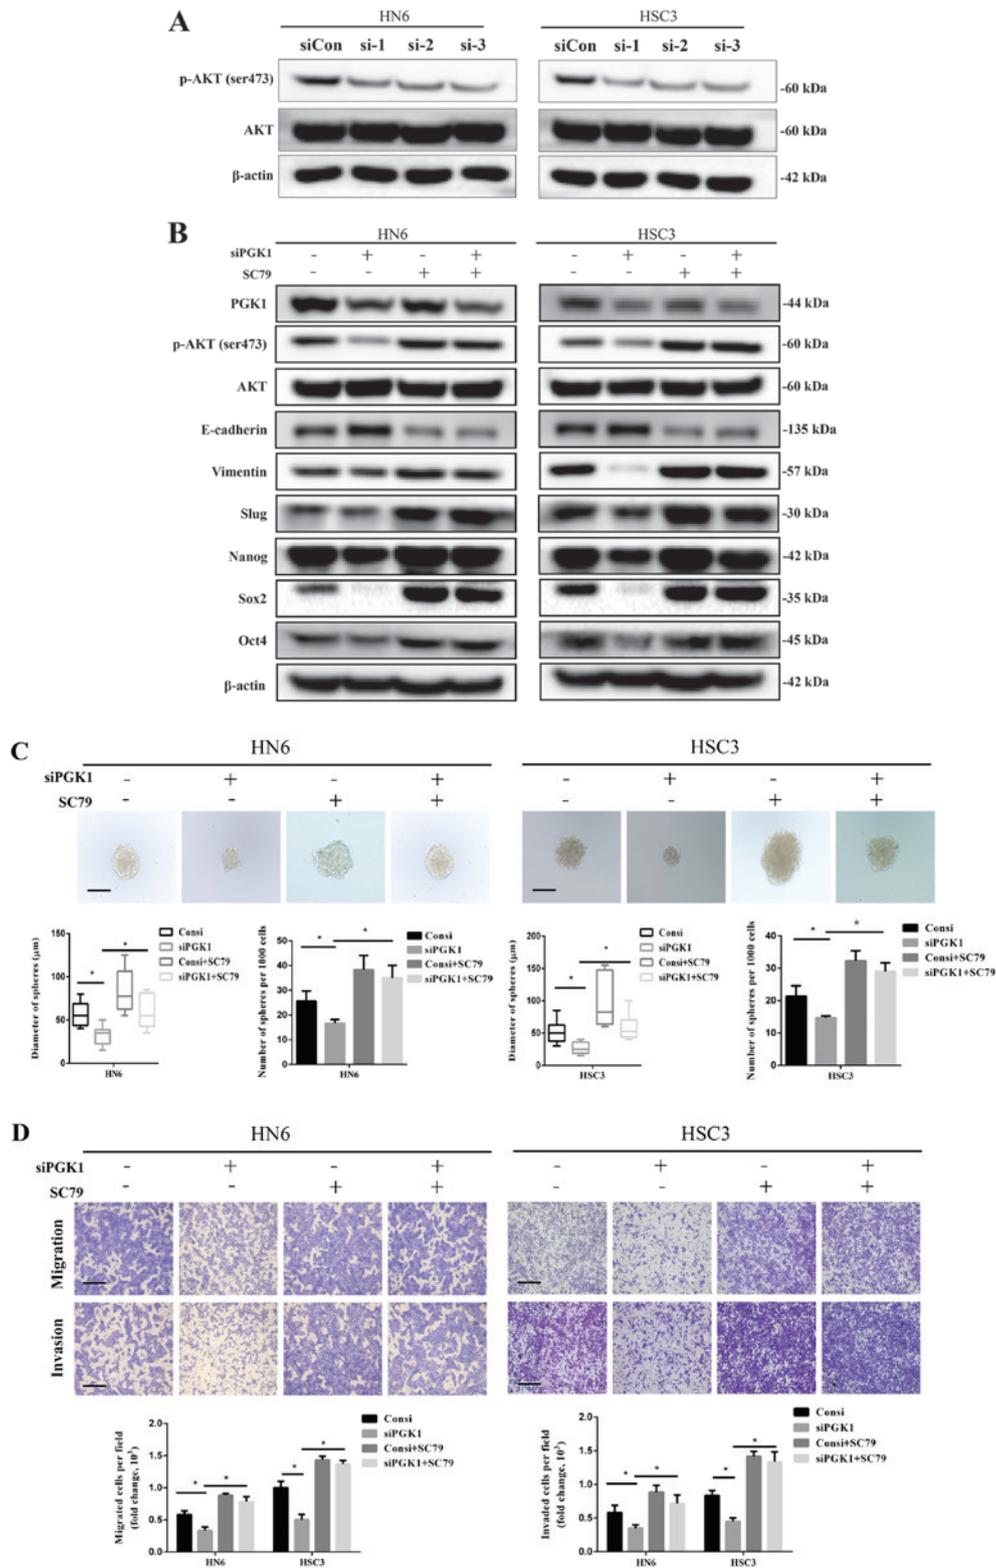

Figure 6. PGK1 promotes stem-like properties and epithelial-mesenchymal transition in oral squamous cell carcinoma cells through the AKT signaling pathway. (A) Western blotting was used to measure the phosphorylation of AKT in HN6 and HSC3 cells after PGK1 knockdown. (B) HN6 and HSC3 cells were treated with SC79 and/or transfected with siPGK1, following which the expression levels of the indicated proteins were measured by western blotting. (C) Sizes and numbers of spheroids formed were measured after HN6 and HSC3 cells were treated with SC79 and/or transfected with siPGK1. Spheroids with diameters $>50 \mu\text{m}$ were displayed. Scale bar, $50 \mu\text{m}$. (D) Transwell assays were used to measure HN6 and HSC3 cell migration and invasion following treatment with SC79 and/or transfection with siPGK1. * $P < 0.05$, $n = 3$. Scale bar, $50 \mu\text{m}$. PGK1, phosphoglycerate kinase 1; Sox-2, SRY-box transcription factor 2; Oct4, octamer-binding transcription factor 4; HIF-1 α , hypoxia-inducible factor-1 α ; si, small interfering RNA; ConsiRNA, control siRNA.

Cell division and proliferation are metabolically active processes within cells. However, energy production

within cancer cells does not particularly depend on the classical oxidative phosphorylation pathway performed by

Table I. Association between PGK1 expression and clinicopathological features in patients with OSCC (n=92).

Clinicopathological features	No. of cases	PGK1 expression		P-value
		High (n)	Low (n)	
Sex				0.052
Male	58	36	22	
Female	34	14	20	
Age				0.809
≥55	56	31	25	
<55	36	19	17	
Differentiation				0.001
Well	16	4	12	
Moderate + poor	76	46	30	
T stage				0.107
T1-2	77	39	38	
T3-4	15	11	4	
Clinical stage				0.008
I-II	59	26	33	
III-IV	33	24	9	
LN metastasis				0.018
N ⁻	68	32	36	
N ⁺	24	18	6	

N⁻, no lymph node metastasis; N⁺, presence of lymph node metastasis.

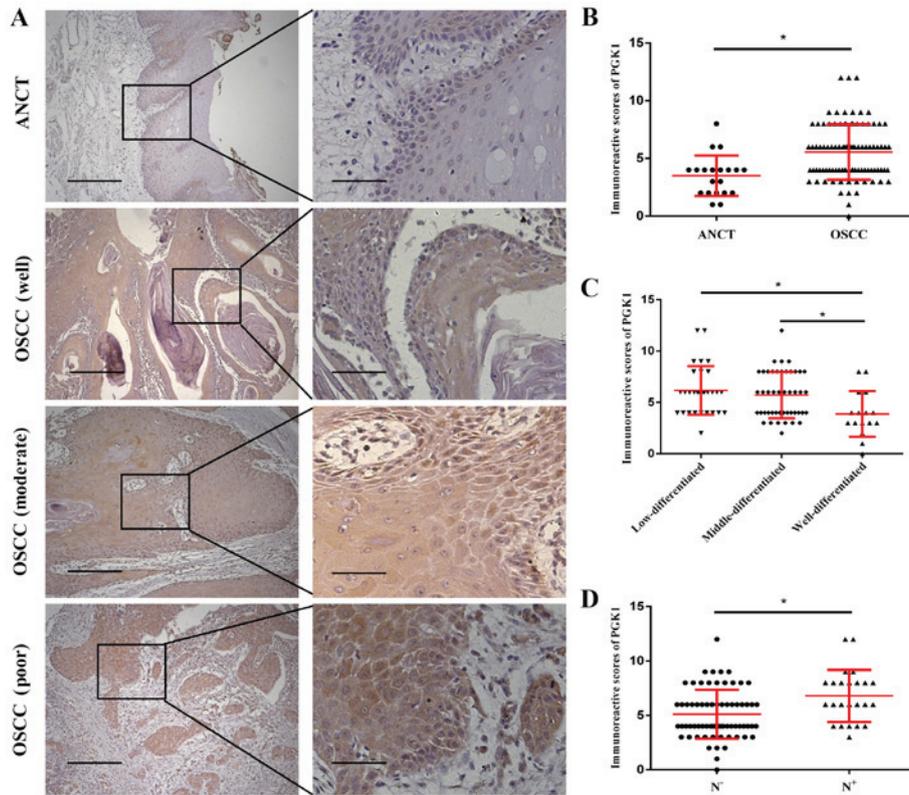

Figure 7. PGK1 expression in OSCC samples. (A) Representative immunohistochemistry images showing that the expression of PGK1 in OSCC specimens at three different stages of differentiation was higher compared with that in ANCT. (B) Comparison of PGK1 expression between OSCC and adjacent noncancerous tissue samples. (C) PGK1 expression is higher in moderately and poorly differentiated OSCC tissues. (D) PGK1 expression is higher in OSCC tissue specimens with lymph node metastasis. *P<0.05. Scale bar, 50 μm (left), 10 μm (right). OSCC, oral squamous cell carcinoma; ANCT, adjacent noncancerous tissue samples; N⁻, no lymph node metastasis; N⁺, presence of lymph node metastasis; PGK1, phosphoglycerate kinase 1.

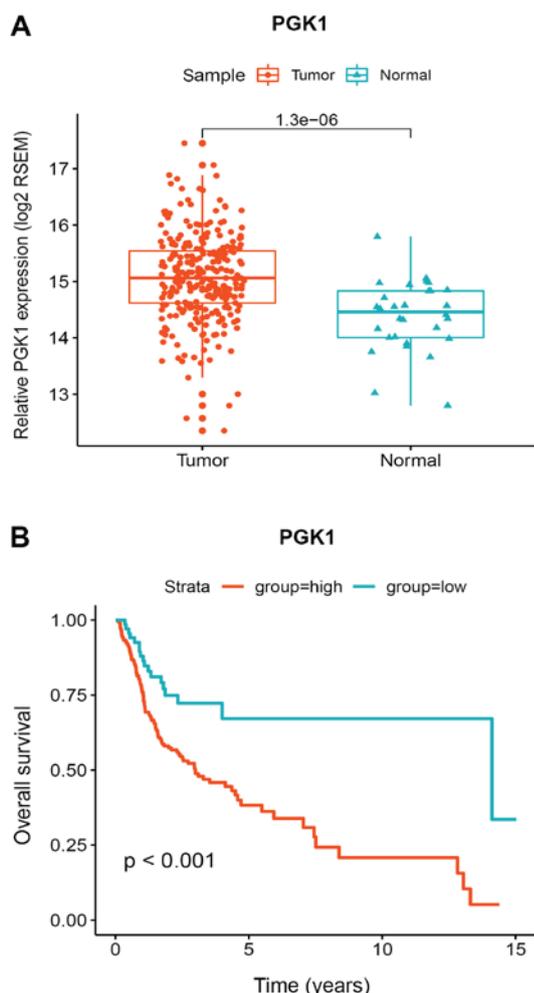

Figure 8. Expression levels of PGK1 in patients with OSCC is associated with overall survival and prognosis. (A) PGK1 mRNA expression in OSCC (n=284) and ANCT (n=30) samples collected from the TCGA database. (B) Kaplan-Meier survival curves for overall survival in OSCC. OSCC, oral squamous cell carcinoma; ANCT, adjacent noncancerous tissue samples; PGK1, phosphoglycerate kinase 1.

mitochondria (44). On the contrary, cancer cells frequently utilize the glycolytic pathway to produce ATP, even when the supply of oxygen is sufficient. This is a process known as the 'Warburg effect' (45). A previous study has found that glutamine starvation can activate PFKP expression, whilst downregulation of PFKP can reverse the invasion and migration of OSCC cells induced by starvation (46). In addition, previous studies have documented that hypoxia is closely associated with tumorigenesis, cell development, invasion and migration in oral cancer (47,48).

Hypoxic environments can be readily found in solid malignant tumors and can lead to alterations in the expression of a number of molecular biomarkers, including HIF, carbonic anhydrase, glucose-transporter-1 and vascular endothelial growth factor (49). HIF-1 α , which is activated under hypoxic conditions, is involved in the regulation of tumor cell propagation, migration, glucose metabolism and angiogenesis (50). It allows cells to adapt to hypoxic environments, contributing to invasion and metastasis. It was previously found that HIF-1 α can promote the malignant progression of esophageal squamous cell carcinoma by regulating the expression specificity

protein 1 (49). In the present study, it was found that both HIF-1 α and PGK1 expression were upregulated due to hypoxia, suggesting an association between these two proteins.

PGK1 is a key enzyme in glycolysis, which converts glyceric acid 1,3-diphosphate to produce glyceric acid 3-phosphate and ATP (28). A number of studies previously found that PGK1 expression is significantly associated with the survival and prognosis of patients with hepatocellular carcinoma, where PGK1 knockdown can inhibit the proliferation of hepatocellular carcinoma cell lines (50,51). PGK1 expression in several tumour tissues was found to be higher compared with that in normal tissues (26), whilst HIF-1 α has been previously shown to directly regulate PGK1 (52). In liver cancer, the expression levels of PGK1 and HIF-1 α in the hepatocellular carcinoma cell line HCCLM9 with high metastasis were higher when compared with those in the hepatocellular carcinoma cell line MHCC97L with low metastasis (26,33), such that PGK1 has also been revealed to regulate cell proliferation and metastasis (32). In addition, PGK1 overexpression can promote the development and metastasis of gastric cancer by activating the C-X-C motif chemokine receptor 4/C-X-C motif chemokine 12/ β -catenin signalling pathway (26). The present study found that 12 h of hypoxia treatment could promote the proliferation of oral cancer cells. The present study also found that hypoxic conditions upregulated the expression of PGK1 and stem cell markers in OSCC cell lines.

EMT is a key mechanism for potentiating invasion and migration in OSCC cells, where the self-renewing and proliferative capacities of tumor stem cells is one of the causes of OSCC recurrence. It has been previously demonstrated that the differential expression of stem cell markers, including CD44, CD133 and ALDH1, in addition to transcription factors, including Oct4, Sox2 and Nanog, serve an important role in clonogenesis in oral squamous cell carcinomas (54,55). In the present study, hypoxia was shown to upregulate the expression of EMT markers promote the migration and invasion of oral cancer cells. Further investigation found that PGK1 knockdown partially reversed the invasion and migration of oral cancer cells under hypoxic conditions.

The AKT signalling pathway is involved in many processes, including proliferation, apoptosis, cancer cell migration and invasion (56). Aberrant activation of the AKT signalling pathway has been previously shown to serve an important role in the malignant progression of cancer (57,58). A previous study has demonstrated that the AKT/NF κ B signalling pathway is involved in the invasion and migration of lung cancer cells, which is closely associated with the maintenance of stem cell characteristics and EMT (59). Another study has also previously found that hypoxia promotes glioma cell proliferation, migration and invasion via PI3K/AKT signalling (58). Results from the present study suggest that the downregulation of PGK1 inhibits the phosphorylation of AKT, whilst the AKT activator SC79 reversed the effects observed following PGK1 knockdown.

Differential observations would have been made if the present study was performed under hypoxic conditions compared with cells grown under normoxic conditions.

A preliminary study of the present study found that following hypoxia treatment for >48 h, the cells were in a poor state of health and could not complete the subsequent proliferation, invasion and migration experiments. Therefore, the method of hypoxia pre-treatment was applied to study the effects of hypoxia on the biological behaviour of tumour cells. The results demonstrated that appropriate hypoxia can promote the malignant progress of OSCC cells, where further study found that moderate hypoxia can promote tumour cell proliferation. This was a limitation of the present study, which remain to be the focus of future research.

To conclude, data from the present study suggest that hypoxia can upregulate PGK1 expression and glycolysis whilst activating the characteristics of oral cancer stem cells and EMT through the AKT pathway. However, the exact mechanism require further clarification.

Funding

The present study was supported by the National Natural Science Foundation project of China (grant nos. 81874128 and 81572660) and Sun Yat-Sen University Clinical Research 5010 Program (grant no. 2015018).

Availability of data and materials

All data generated or analyzed during this study are included in this article.

Authors' contributions

JH developed the concept of the project. YZ designed and performed the experiments, analysed the results and wrote the manuscript. HC performed the immunohistochemical staining. YL collected and analysed clinical specimens and clinical data. FW and YZ were involved in statistical analysis of the obtained results. All authors read and approved the final version of the manuscript.

Ethics approval and consent to participate

The removal of tissue samples from patients was approved by the ethical review committee of the Affiliated Stomatological Hospital of Sun Yat-sen University (Guangzhou, China). The experiments were performed with the understanding and written consent of each subject. The study methodologies conformed to the standards set by the Declaration of Helsinki.

Patient consent for publication

Not applicable.

Competing interests
