Abstract. N-acetyl-seryl-aspartyl-lysyl-proline (Ac-SDKP) is a natural tetrapeptide that is released from thymosin β 4 by prolyl oligopeptidases. It is hydrolyzed by the key enzyme of the renin-angiotensin system, angiotensin-converting enzyme (ACE). The aim of the present study was to investigate the alterations in Ac-SDKP and the ACE/angiotensin II (Ang II)/angiotensin II type 1 (AT1) receptor axis and its impact on the pathogenesis and development of silicotic fibrosis. For *in vivo* studies, a HOPE MED 8050 exposure control apparatus was used to establish different stages of silicosis in a rat model treated with Ac-SDKP. For *in vitro* studies, cultured primary lung fibroblasts were induced to differentiate into myofibroblasts by Ang II, and were pretreated with Ac-SDKP and valsartan. The results of the present study revealed that, during silicosis development, ACE/Ang II/AT1 expression in local lung tissues increased, whereas that of Ac-SDKP decreased. Ac-SDKP and the ACE/AT1/Ang II axis were inversely altered in the development of silicotic fibrosis. Ac-SDKP treatment had an anti-fibrotic effect *in vivo*. Compared with the silicosis group, the expression of α -smooth muscle actin (α -SMA), Collagen (Col) I, Fibronectin (Fn) and AT1 were significantly downregulated, whereas matrix metalloproteinase-1 (MMP-1)

expression and the MMP-1/tissue inhibitor of metalloproteinases-1 (TIMP-1) ratio was increased in the Ac-SDKP treatment group. *In vitro*, pre-treatment with Ac-SDKP or valsartan attenuated the expression of α -SMA, Col I, Fn and AT1 in Ang II-induced fibroblasts. In addition, MMP-1 expression and the MMP-1/TIMP-1 ratio were significantly higher in Ac-SDKP and valsartan pre-treatment groups compared with the Ang II group. In conclusion, the results of the present study suggest that an imbalance between Ac-SDKP and ACE/Ang II/AT1 molecules promotes the development of silicosis and that Ac-SDKP protects against silicotic fibrosis by inhibiting Ang II-induced myofibroblast differentiation and extracellular matrix production.

Introduction

Silicosis is caused by long-term inhalation of silicon dioxide dust in professional activities and its basic pathological features include the formation of silicotic nodules and lung fibrosis (1). N-acetyl-seryl-aspartyl-lysyl-proline (Ac-SDKP) is a natural tetrapeptide formed from its precursor, thymosin β 4, released by prolyl oligopeptidases (2). Ac-SDKP has antifibrosis effects and is expressed in human and animal tissues (3,4). The downregulation of Ac-SDKP expression is associated with organ fibrosis (5,6). The renin-angiotensin system (RAS) is a key mediator of lung fibrosis (7,8); the key enzyme of RAS, angiotensin-converting enzyme (ACE), consists of 2 catalytic domains, namely the C and N domains (9). The C domain catalyzes angiotensin (Ang) I to form Ang II (10). Ang II is the major active protein of RAS and its fibrotic effect is primarily mediated by angiotensin II type 1 (AT1), which includes the induction of inflammatory responses as well as increased expression of transforming growth factor- β (TGF- β), proliferation of fibroblasts and extracellular matrix (ECM) deposition (11-14). Ac-SDKP is cleaved by the N domain of ACE and its plasma and tissue levels therefore significantly increase following ACE inhibition (3,15). The role of ACE in producing the pro-fibrotic molecule Ang II and degrading the anti-fibrotic molecule Ac-SDKP suggests that the interaction between Ac-SDKP and RAS may be important in silicosis. In the present study, changes in Ac-SDKP and Ang II signaling during the development of silicosis were investigated. The

protective effect of Ac-SDKP and its potential association with Ang II signals was also investigated.

Materials and methods

Materials. A total of 100 specific pathogen-free male Wistar rats (3 weeks of age) were obtained from the Vital River Laboratory (Beijing, China). The rats were housed in a temperature-controlled facility at $22\pm 2^{\circ}\text{C}$, $50\pm 10\%$ humidity and 0.03–0.04% CO_2 , with a 12 h light/dark cycle and received food and water according to the guidelines established by the North China University of Science and Technology (16). HOPE MED 8050 exposure control apparatus was supplied by Tianjin Hope Industry and Trade Co., Ltd. (Tianjin, China). SiO_2 was obtained from Sigma Aldrich (Merck KGaA, Darmstadt, Germany). The silica content of SiO_2 was $>99\%$ and its dust particle size distribution was as follows: 97% $<5\ \mu\text{m}$ diameter, 80% $<3\ \mu\text{m}$ diameter (according to the supplier). Ac-SDKP was supplied by Bachem (Bubendorf, Switzerland). Ang II and valsartan were purchased from Sigma-Aldrich (Merck KGaA). Ac-SDKP (cat. no. CSB-E0925r) and Ang II (cat. no. CSB-E04494r) ELISA kits were obtained from CUSABIO (Wuhan, Hubei, China). The PV-6000 1-step polymer detection system for mouse, rabbit and rat antibodies were acquired from Beijing Zhongshan Jinqiao Biotechnology Co., Ltd. (Beijing, China). Enhanced chemiluminescence reagent (cat. no. RPN2232) was supplied by GE Healthcare (Chicago, IL, USA). Masson's trichrome stain was supplied by Baso Diagnostics, Inc. (Wuhan, China). Polyclonal rabbit anti-collagen (Col) I (cat. no. ab34710), anti α -smooth muscle actin (SMA; cat. no. ab32575), anti-Fibronectin (Fn) (cat. no. ab45688), rabbit monoclonal anti-AT1 (cat. no. ab124734) and mouse monoclonal anti-ACE (cat. no. ab117334) were purchased from Abcam (Cambridge, UK). Polyclonal rabbit anti-matrix metalloproteinase (MMP)-1 (cat. no. EL800296-50) and anti-tissue inhibitor of metalloproteinases-1 (TIMP-1; cat. no. EL800628-50) were obtained from Eterlife, Ltd. (Birmingham, UK). Polyclonal mouse anti- β -actin (cat. no. sc-47778) and polyclonal rabbit anti-GAPDH (cat. no. sc-25778) were purchased from Santa Cruz Biotechnology, Inc. (Dallas, TX, USA). Dulbecco's modified Eagle's medium (DMEM) was obtained from Biological Industries USA (Cromwell, CT, USA). Fetal bovine serum (FBS) was purchased from Gibco (Thermo Fisher Scientific, Inc., Waltham, MA, USA).

Animal studies. All animal studies were approved by the Institutional Animal Care and Use Committee of North China University of Science and Technology. HOPE MED 8050 exposure control apparatus was used to create the silicosis model. The settings were as follows: Cabinet temperature, $20\text{--}25^{\circ}\text{C}$; humidity, 70–75%; pressure, -50 to $+50$ Pa; oxygen concentration, 20%; flow rate of SiO_2 : 3.0–3.5 m/min; dust mass concentration, 2,000 mg/m³. Each rat inhaled SiO_2 for 3 h per day for 0, 2, 4, 8, 12 and 16 weeks. The rats were randomly divided into 6 groups ($n=10$) and inhaled dust for 0, 2, 4, 8, 12 and 16 weeks to observe dynamic changes during the development of silicosis. To determine the anti-silicotic effect of Ac-SDKP, rats were randomly divided into 3 groups ($n=10$): i) 16 week control (treated with 0.9% saline for

16 weeks); ii) 16 week silicosis (treated with 0.9% saline 48 h before SiO_2 inhalation and thereafter for 16 weeks); and iii) Ac-SDKP post-treatment (inhaled SiO_2 and then treated with 0.9% saline for 8 weeks and Ac-SDKP for another 8 weeks). Ac-SDKP (800 mg/kg/day) or control (0.9% saline) was administered via a mini-osmotic pump implanted into the abdominal cavity as previously described (17). The rats were anesthetized, and sera and lung samples were collected and frozen at -80°C until subsequent analysis.

Cell culture. Rats ($n=10$) were anaesthetized and lung tissue was removed. Lung fibroblasts were isolated from minced tissue, as previously described (18) and plated on 25-cm² plates containing DMEM supplemented with 10% FBS and 1% penicillin-streptomycin. The cells were cultured in a humidified atmosphere containing 5% CO_2 at 37°C . Cells at 80% confluence were cultured in FBS-free DMEM for 24 h, when most cells were quiescent. The induction effect of Ang II (10^{-7} mol/l) on the transformation of lung fibroblasts into myofibroblasts was studied at different time points (0, 5, 15 and 30 min, and 1, 3, 6, 12, 24 and 48 h) at 37°C . Primary lung fibroblasts were divided into four groups and cultured for 24 h at 37°C : i) Control (FBS-free DMEM); ii) Ang II (10^{-7} mol/l); iii) Ang II + Ac-SDKP (10^{-8} mol/l); and iv) Ang II + valsartan (10^{-6} mol/l).

Lung histopathology. The right lower lungs were fixed in 4% paraformaldehyde at 4°C for 24 h, embedded in paraffin, sectioned at $5\ \mu\text{m}$ and subjected to hematoxylin and eosin (H&E) and Masson trichrome staining at room temperature for pathophysiological observation. For H&E staining, the tissues sections were stained with hematoxylin for 30 sec and with stain 1% eosin solution for 1 min. For Masson trichrome staining, the tissue sections were stained with Weigert's working hematoxylin for 10 min. Subsequently, the sections were washed in running tap water for 5 min. Biebrich scarlet staining was subsequently performed for 5 min. Phosphomolybdic acid was added for 10 min and then the solution was discarded. Tissue samples were transferred directly into Aniline blue for 5 min and rinsed in distilled water. Images in each rat were obtained from 5 randomly selected fields of view using Olympus DP80 light microscope (magnification, $\times 200$; Olympus Corporation, Tokyo, Japan).

Immunohistochemistry (IHC). IHC of lung tissue sections ($5\ \mu\text{m}$) and cultured fibroblasts (passage 9) was performed. Paraffin embedded sections were deparaffinized, rehydrated and underwent removal of endogenous peroxidase with 3% H_2O_2 and antigen retrieval was performed using 0.01 M citrate buffer. Following blocking with 5% bovine serum albumin (Sigma-Aldrich, Merck KGaA) in 0.1 M phosphate-buffer saline (PBS) for 30 min at room temperature to reduce nonspecific binding, samples were incubated with a primary antibody against α -SMA (1:200; cat. no. ab32575; Abcam) overnight at 4°C , followed by incubation with a goat anti-mouse/rabbit secondary antibody (cat. no. PV-6000, ready to use solution; OriGene Technologies, Inc., Beijing, China) at 37°C for 1 h. Immunoreactivity was visualized with 5% 3,3'-diaminobenzidine (cat. no. ZLI-9018; OriGene Technologies, Inc., Beijing, China) at room temperature for

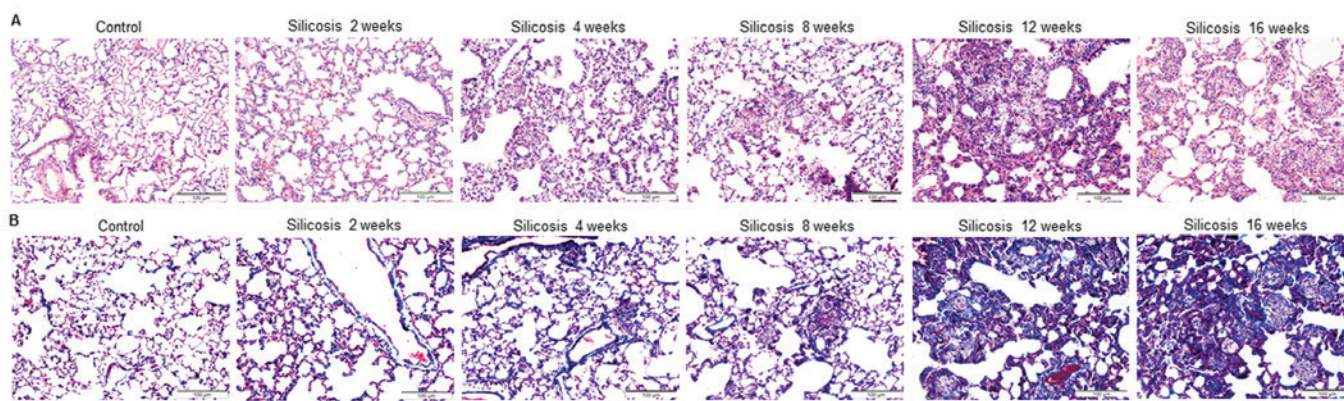

Figure 1. Histomorphological evaluation of the lung tissues. (A) Hematoxylin and eosin and (B) Masson stained lung tissues. Scale bars, 100 μ m.

5 min. Brown staining was considered positive. PBS, instead of primary antibody, was used as a negative control and α -SMA staining of vascular smooth muscle cells was used as a positive control. Images were obtained from 5 separate randomly selected fields of view using the Olympus DP80 (magnification, $\times 200$).

Western blotting. Total proteins were extracted from lung tissues or cells. Lung or cultured fibroblasts were lysed with radioimmunoprecipitation assay (RIPA) buffer (1% NP-40, 0.5% sodium deoxycholate, 0.1% SDS, 150 mM NaCl, 1 mM EDTA, and 50 mM Tris-HCl, pH 7.5) and centrifuged at 14,000 \times g for 10 min at 4°C. Protein concentrations in supernatants were measured with a Bradford assay (Beijing Solarbio Science & Technology Co., Ltd., Beijing, China). Protein samples (20 μ g/lane) were separated by 10% SDS-PAGE and transferred onto polyvinylidene fluoride membranes. Membranes were blocked with 5% non-fat milk for 2 h at room temperature and incubated overnight at 4°C with the primary antibody against Col I, α -SMA, Fn, ACE and AT1 (all 1:500) followed by a peroxidase-labeled affinity-purified secondary antibody to rabbit/mouse IgG (1:5,000, cat. no. 074-1506, Kirkegaard & Perry Laboratories, Inc., Gaithersburg, MD, USA) for 2 h at 37°C. Target bands were visualized by the addition of an Enhanced Chemiluminescence Prime Western Blotting Detection reagent (GE Healthcare, Chicago, IL, USA). The density of specific bands was analyzed using Image-Pro Plus image processing software (version 6.0; Media Cybernetics, Inc., Rockville, MD, USA) and the results were normalized to β -actin or GAPDH (both 1:500).

ELISA assay. Lung tissues were lysed with RIPA and the levels of Ac-SDKP and Ang II were determined by using the corresponding ELISA kits according to the manufacturer's protocol.

Statistical analysis. All experiments were performed in triplicate. The results are expressed as the mean \pm standard error of the mean. Comparisons between multiple independent groups were performed using one-way analysis of variance followed by a post hoc analysis with the Bonferroni test. $P < 0.05$ was considered to indicate a statistically significant difference.

Results

Morphological alterations in lungs of rats exposed to silica.

The results of HE staining revealed that in the normal controls, the alveolar walls were thin and there was no obvious inflammatory cell infiltration (Fig. 1A). In the 2-week silicosis group, macrophages were observed in the alveoli and the alveolar wall was wider in appearance. The 4-week silicosis group exhibited isolated cell nodules that contained macrophages. The 8- and 12-week silicosis groups had significantly wider alveolar walls and a greater number of silicotic nodules. The 16-week silicosis group exhibited an increase in silicotic nodule volume, nodule fusion, interstitial fibrosis and cell fibrous nodules (Fig. 1A). Blue purple Masson trichrome staining was observed in the nodules and interstitial fibrosis area, indicating collagen deposition, which gradually increased with model preparation time and most distinct in the 16-week silicosis group (Fig. 1B).

Expression of ACE, Ang II, AT1 and Ac-SDKP in the lungs of rats exposed to silica. To investigate whether ACE/Ang II/AT1 proteins are involved in the pathogenesis of silicotic fibrosis, the expression of ACE, Ang II and AT1 in rat lungs was assessed. The expression of ACE, Ang II and AT1 was increased in the 2-, 4-, 8-, 12- and 16-week silicosis groups compared with the control group (Fig. 2A and B). Ac-SDKP expression in the 2-week silicosis group was significantly higher compared with the control group, whereas expression in the 4-, 8-, 12- and 16-week silicosis groups decreased (Fig. 2C).

Expression of α -SMA, Col I and Fn in silicosis and in fibroblasts induced by Ang II. Western blotting revealed that, compared with the control group, α -SMA, Col I and Fn expression was gradually increased in the 4-, 8-, 12- and 16-week silicosis groups (Fig. 3A). In response to Ang II stimuli, the cultured rat lung fibroblasts underwent differentiation and produced excessive amounts of ECM *in vitro*. Ang II stimulated the expression of α -SMA, Col I and Fn, which increased with treatment duration (Fig. 3B). Based on these findings and results of a previous study (19), 24 h was selected as the optimal treatment time for subsequent studies.

Ac-SDKP regulates ACE, Ang II and AT1 during silicosis and the expression of AT1 in fibroblasts induced by Ang II. Compared with the 16-week silicosis group, treatment with

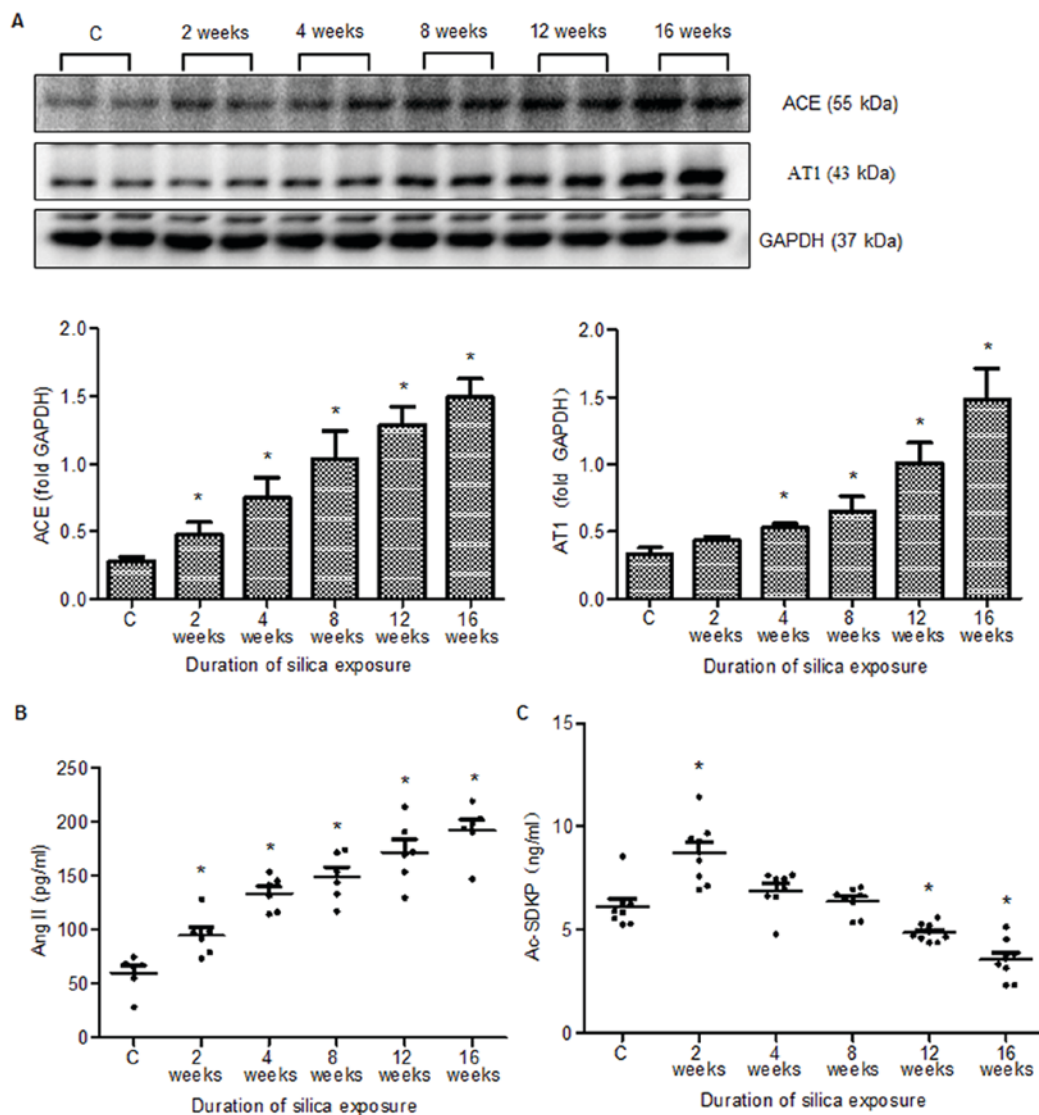

Figure 2. Expression of ACE, Ang II, AT1 and Ac-SDKP in rats. (A) ACE and AT1 expression in silicotic rat lung tissues were assessed by western blotting. (B) Ang II and (C) Ac-SDKP expression in rat silicotic lung tissues was assessed using ELISA. *P<0.05 vs. the control group. ACE, angiotensin-converting enzyme; Ang II, angiotensin II; Ac-SDKP, N-acetyl-seryl-aspartyl-lysyl-proline; AT1, angiotensin II type 1.

Ac-SDKP resulted in decreased AT1 expression. The expression of ACE and Ang II (Fig. 4A and B) in the Ac-SDKP treatment group decreased, but was not statistically significant. The Ang II-dependent increase in AT1 expression was also inhibited following Ac-SDKP and valsartan treatment (Fig. 4C).

Ac-SDKP attenuates the expression of α -SMA, Col I and Fn during silicosis and in Ang II-induced fibroblasts. IHC staining revealed that α -SMA-positive myofibroblasts were located in the nodules and distributed in the interstitial fibrotic area in the 16-week silicosis group (Fig. 5). Ac-SDKP treatment reduced the expression of α -SMA. Compared with the 16-week silicosis group, α -SMA, Col I and Fn expression levels were significantly downregulated in the Ac-SDKP post-treatment group (Fig. 6). Subsequently, α -SMA expression was assessed using IHC staining. Compared with the control group, α -SMA expression was demonstrated to be increased following Ang II induction in cultured lung fibroblasts. Compared with the Ang II group, the expression of α -SMA was decreased in

the Ac-SDKP and valsartan treatment groups (Fig. 7). The Ang II-dependent increase in α -SMA, Col I and Fn expression was also inhibited following Ac-SDKP and valsartan treatment (Fig. 8).

Ac-SDKP regulates MMP-1, TIMP-1 and the MMP-1/TIMP-1 ratio during silicosis and in fibroblasts induced by Ang II. Western blotting demonstrated that the expression of TIMP-1 was markedly increased in the silicosis group compared with the control group, whereas MMP-1 expression and the MMP-1/TIMP-1 ratio was significantly decreased (Fig. 9A). Treatment with Ac-SDKP increased the expression of MMP-1 and the MMP-1/TIMP-1 ratio. No significant differences in TIMP-1 expression were observed between the Ac-SDKP post-treatment and silicosis groups. *In vitro* experiments revealed that MMP-1 expression and the MMP-1/TIMP-1 ratio was reduced compared with the control and the expression of TIMP-1 was markedly increased in fibroblasts induced by Ang II (Fig. 9B). Ac-SDKP or valsartan treatment upregulated the expression of MMP-1 and enhanced the MMP-1/TIMP-1

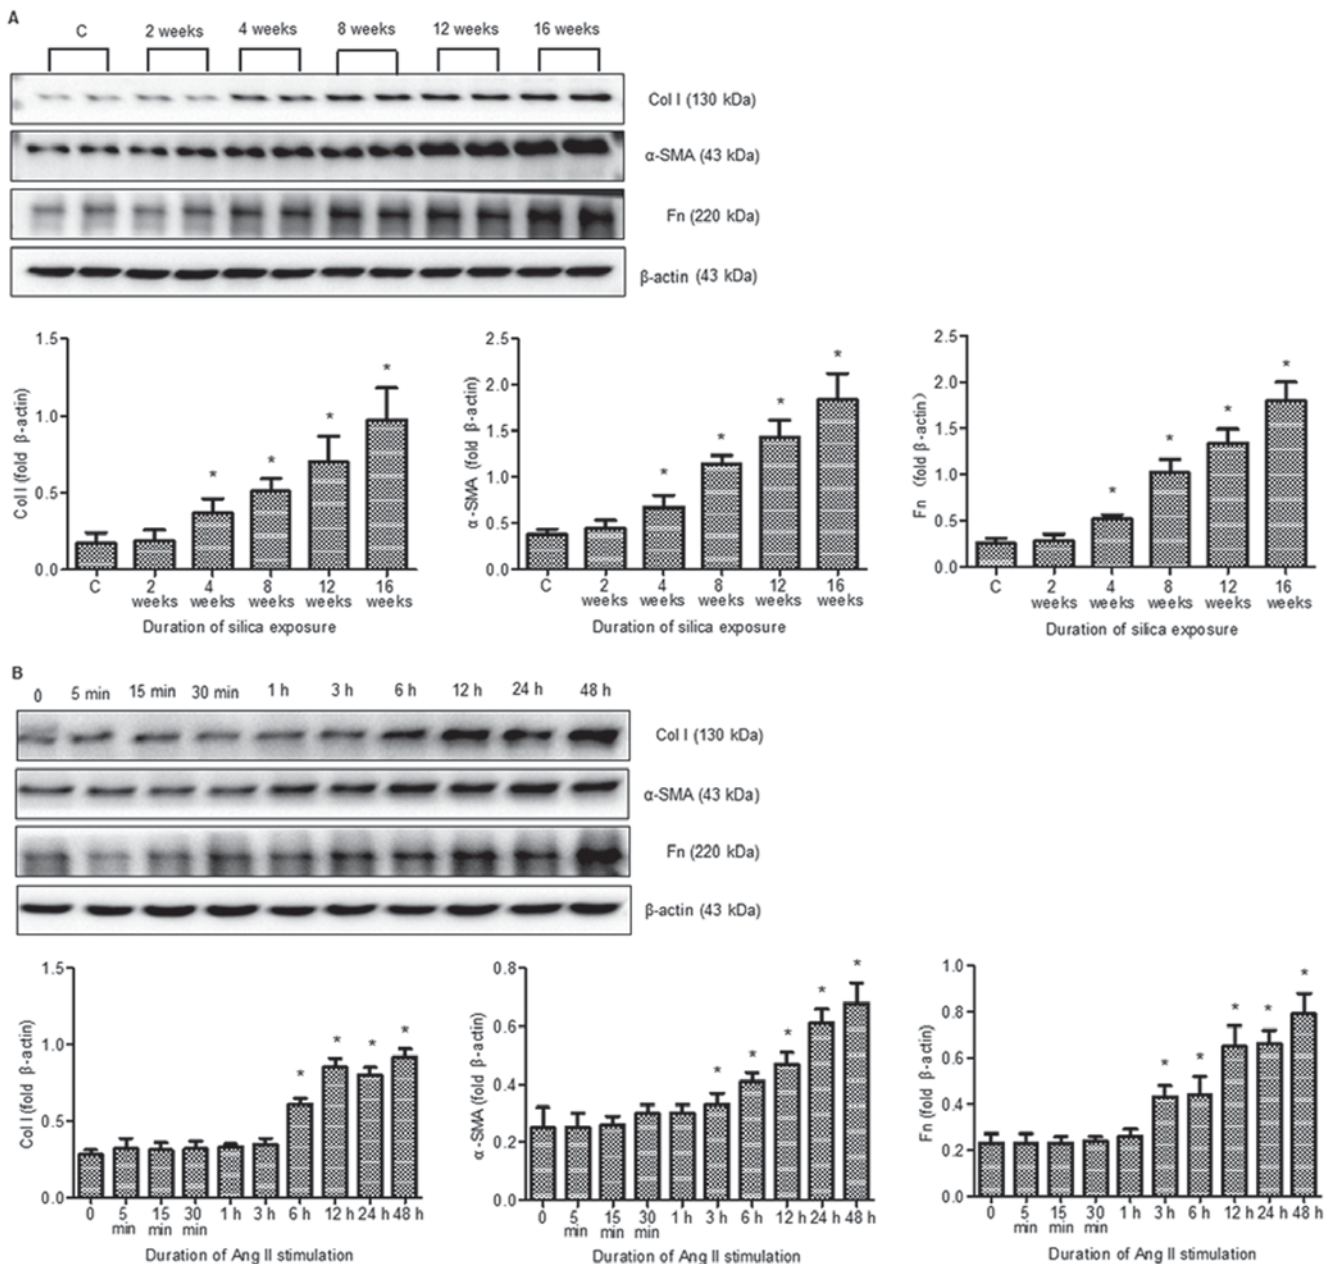

Figure 3. Expression of α -SMA, Col I and Fn in silicosis and in Ang-II stimulated fibroblasts. α -SMA, Col I and Fn expression in (A) lung tissues and (B) fibroblasts at different time points was assessed using western blotting. * $P < 0.05$ vs. the control group. α -SMA, α -smooth muscle actin; Col I, collagen I; Fn, Fibronectin; Ang II, angiotensin II; C, control.

ratio, whereas it had no significant effect on the expression of TIMP-1.

Discussion

In the present study, a rat silicosis model was established using HOPE MED8050 exposure control apparatus. This system is a non-invasive instrument that allows animal inhalation of silica particles and may be set to a certain dust concentration. Compared with intratracheal administration of silica dust (20,21), using the dynamic pollution control system facilitated the establishment of an ideal silicosis model. Histopathological observations demonstrated that, following inhalation of SiO_2 for 4 weeks, silicotic nodules

containing macrophages developed in the lung tissues of rats. Furthermore, the number of silicotic nodules increased after 8 and 12 weeks of inhalation. Fibrous and cellular silicotic nodules with diffuse interstitial fibrosis were observed in rats at 16 weeks. Myofibroblasts are α -SMA-expressing cells that originate from epithelial-mesenchymal transition (22), endothelial-to-mesenchymal transition (23), pericyte trans-differentiation (24) and pleural mesothelial cells (25) or pulmonary interstitial fibroblasts (26). Myofibroblasts serve a pivotal role in wound healing; however, the unusual persistent proliferative and migratory properties of myofibroblasts leads to an excessive accumulation of the ECM and lung fibrosis. In the present study, IHC revealed that α -SMA-positive myofibroblasts surrounded macrophages and were irregularly

distributed in interstitial fibrotic areas. Western blotting further demonstrated that α -SMA protein expression in the 4-, 8-, 12- and 16-week silicosis groups gradually increased, suggesting the accumulation of a large number of activated myofibroblasts in the silicosis model. These findings suggested that a silicosis model was successfully established using a HOPE-MED8050 dynamic dust system.

RAS is a key mediator that is involved in the pathogenesis of tissue remodeling, including the lungs (5). Studies have reported that the expression of ACE in bronchoalveolar lavage fluid is higher (27) and the angiotensinogen gene is

overexpressed in the lung tissues of patients with pulmonary fibrosis (28). This contributes to increase Ang II levels in pulmonary fibrosis. It has been suggested that Ang II, acting via the AT1 receptor, modulates pro-fibrotic downstream effects, including inflammatory cell recruitment, cellular proliferation and the accumulation of ECM (8). In the present study it was demonstrated that the expression of ACE, Ang II and AT1 in the lung tissue of rats increased with time, which was consistent with the degree of silicosis. Differentiation of fibroblasts into myofibroblasts is a critical event in fibrosis. Ang II serves a major role in fibrosis by promoting myofibroblast

Figure 6. differentiation (29,30). The expression of α -SMA, Col I and Fn in Ang II-stimulated lung fibroblasts was demonstrated to be time-dependent in the present study, thereby confirming that myofibroblast differentiation may be induced by Ang II from lung fibroblasts and suggesting that the increased ECM deposition in the rat silicosis model may be associated with Ang II elevation *in vivo*. Silicosis in the rat model was mediated, at least partially, by activation of the RAS signaling pathway.

Ac-SDKP is an ACE substrate that demonstrates meaningful anti-fibrotic effects in various experimental models of fibrotic disease (3). Ac-SDKP has been reported to inhibit cell proliferation and myofibroblast differentiation via weakening TGF- β -induced myofibroblasts against decapentaplegic homolog 2 (Smad2)/3 signaling effects (31-33). It has also

been demonstrated that Ac-SDKP treatment promotes the expression of Smad7, which antagonizes Smad2 activity (34). Both RAS and TGF- β have been described as important regulators of the fibrotic disease (35,36). Ang II and TGF- β 1 do not appear to act independently from one another, but rather as part of a signaling network in cardiac remodeling and fibrosis (14,37). Therefore, the interaction between Ac-SDKP and RAS in fibrosis requires further investigation. In the present study, it was observed that Ac-SDKP levels in lung tissues were increased in the 2-week silicosis group compared with the control group, whereas the expression of Ac-SDKP decreased gradually at subsequent time points. Decreased Ac-SDKP expression and increased ACE, Ang II and AT1 expression may result in an imbalance between pro-fibrotic and anti-fibrotic molecules, thereby facilitating the occurrence and development of silicosis. In addition, the results of the present study revealed that Ac-SDKP treatment did not significantly affect ACE or Ang II levels, whereas Ac-SDKP did downregulate the expression of AT1 *in vivo* and inhibited myofibroblast differentiation and ECM synthesis. Ac-SDKP had the same effect as valsartan, inhibiting Ang II-induced myofibroblast differentiation and decreasing Col I and Fn accumulation *in vitro*. The fibrogenic process is associated with an imbalance in MMPs/TIMPs, which results in excessive expression of components of the ECM. MMP-1 serves an important role in fibrosis by preferentially degrading Col I (38). In contrast, TIMP-1 moderately inhibits the activity of MMP1 (39). In the present study, Ac-SDKP treatment increased the expression levels MMP-1 and the MMP-1/TIMP-1 ratio *in vivo* and *in vitro*. The results of the present study therefore suggest that Ac-SDKP may effectively protect lung tissues against silicosis fibrosis and serve a vital role in inhibiting the Ang II-induced myofibroblast differentiation and accumulation of ECM in silicosis.

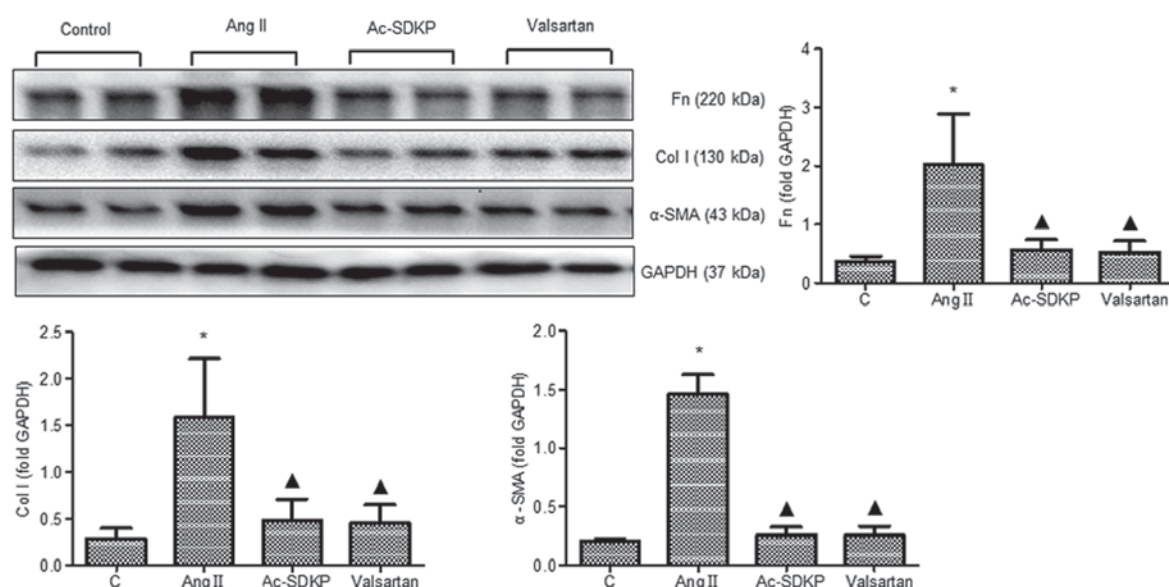

Figure 8. Ac-SDKP attenuates the expression of α -SMA, Col I and Fn in Ang II-stimulated fibroblasts. α -SMA, Col I and Fn expression in fibroblasts were assessed using western blotting. * $P < 0.05$ vs. the control group; * $P < 0.05$, compared with Ang II group. Ac-SDKP, N-acetyl-seryl-aspartyl-lysyl-proline; α -SMA, α -smooth muscle actin; Fn, Fibronectin; Col I, collagen I; C, control.

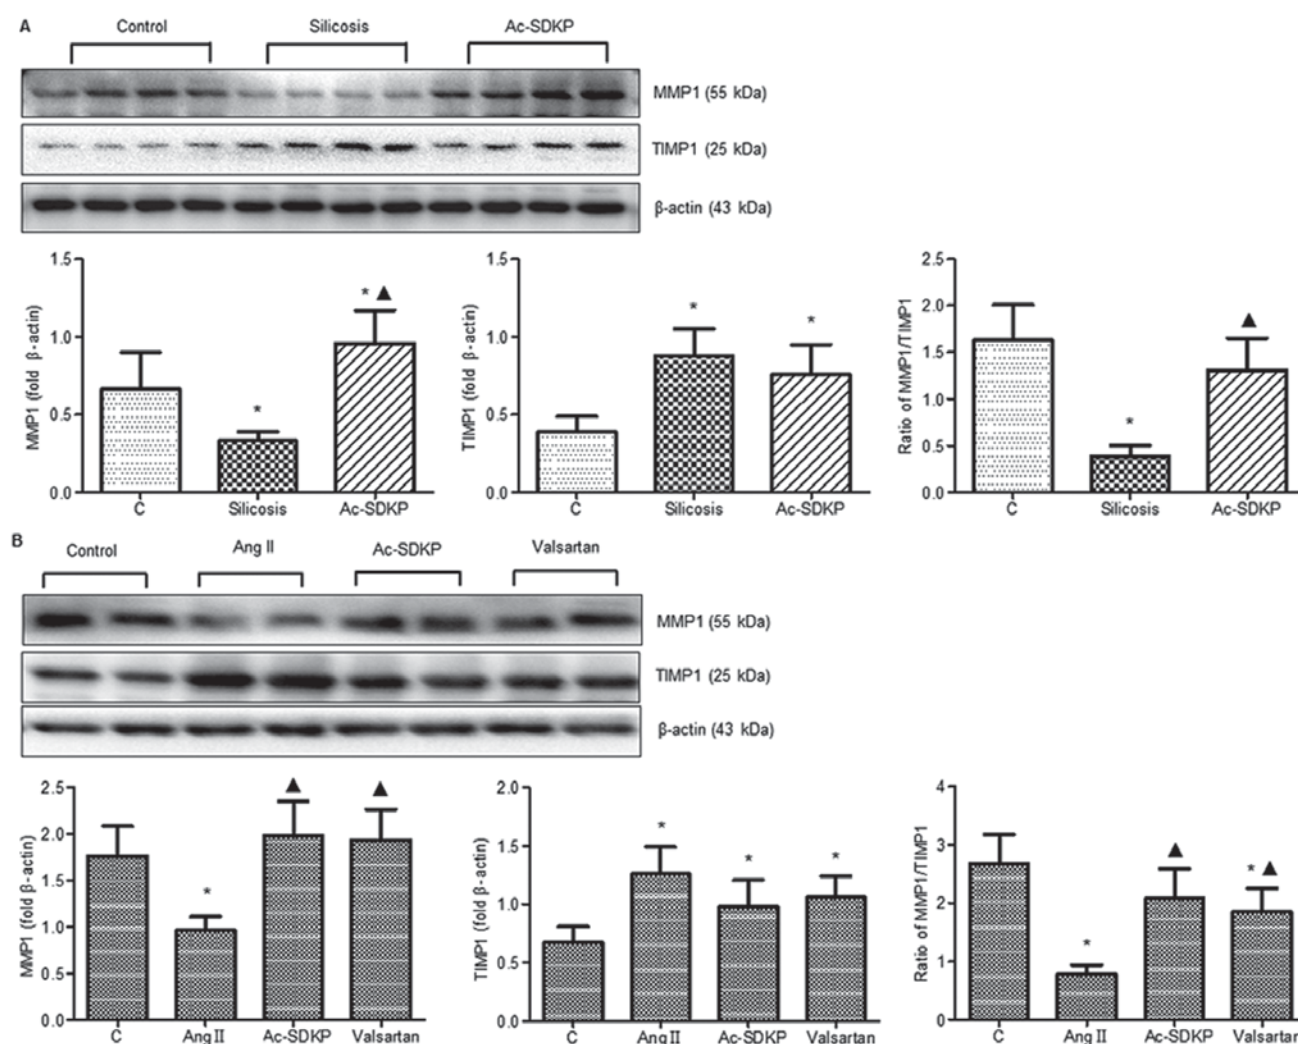

Figure 9. Ac-SDKP regulates the expression of MMP-1, TIMP-1 and the MMP-1/TIMP-1 ratio in silicosis and in Ang II-stimulated fibroblasts. MMP-1 and TIMP-1 expression and the MMP-1/TIMP-1 ratio were assessed in (A) lung tissues and (B) fibroblasts using western blotting. * $P < 0.05$ vs. the control group; * $P < 0.05$, compared with Ang II group. Ac-SDKP, N-acetyl-seryl-aspartyl-lysyl-proline; MMP-1, matrix metalloproteinase-1; TIMP-1, tissue inhibitor of metalloproteinases-1; C, control.

In summary, the results of the present study suggest that an imbalance between Ac-SDKP and ACE/Ang II/AT1 molecules promotes the development of silicosis. Ac-SDKP blocked fibroblast differentiation induced by Ang II and inhibited ECM production, thereby preventing the development of silicotic fibrosis. As Ac-SDKP is inhibited by ACE *in vivo*, the authors of the present study intend to use an ACE inhibitor to determine if similar anti-fibrosis results can be observed. The present study indicates a possibility of use of Ac-SDKP as an inhibitor of RAS for the treatment of silicosis.
