Abstract. Inflammatory bowel disease (IBD) is a chronic, idiopathic inflammatory disease of the small and/or large intestine. Endothelial expression of inflammatory mediators, including cytokines and adhesion molecules, serves a critical role in the initiation and progression of IBD. The dietary flavonoid, kaempferol, has been reported to inhibit expression of inflammatory mediators; however, the underlying mechanisms require further investigation. In the present study, a novel molecular mechanism of kaempferol against IBD was identified. The potential anti-inflammatory effect of kaempferol in a cellular model of intestinal inflammation was assessed using lipopolysaccharide (LPS)-induced rat intestinal microvascular endothelial cells (RIMVECs), and an underlying key molecular mechanism was identified. RIMVECs were pretreated with kaempferol of various concentrations (12.5, 25 and 50 μ M) followed by LPS (10 μ g/ml) stimulation. ELISA was used to examine the protein levels of tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β), IL-6, intercellular adhesion molecule-1 (ICAM-1) and vascular cell adhesion molecule-1 (VCAM-1) in the supernatant. Protein expression levels of Toll-like receptor 4 (TLR4), nuclear factor- κ B (NF- κ B) p65, inhibitor of NF- κ B, mitogen-activated protein kinase p38 and signal transducer and activator of transcription (STAT) in cells were measured by western blotting. Kaempferol significantly reduced the overproduction of TNF- α , IL-1 β , interleukin-6, ICAM-1 and VCAM-1 induced by LPS, indicating the negative regulation of kaempferol in

TLR4, NF- κ B and STAT signaling underlying intestinal inflammation. The present results provide support for the potential use of kaempferol as an effective therapeutic agent for IBD treatment.

Introduction

Inflammatory bowel disease (IBD) primarily comprises two principal conditions, Crohn's disease and ulcerative colitis (UC), characterized by chronic gastrointestinal inflammation with alternating periods of relapse and remission (1). A variety of inflammatory mediators are involved in the pathogenesis of IBD, including tumor necrosis factor- α (TNF- α), interleukin-1 β (IL-1 β), IL-6 and intercellular adhesion molecule-1 (ICAM-1) (2). Excessive inflammatory mediators may lead to edema, ulceration and carcinogenesis of colon tissue (2,3). Therefore, effective regulation of the secretion of inflammatory factors is essential for IBD treatment.

The etiology of IBD is not yet completely understood; it is believed that a complex interaction among genetic, immunological, metabolic, vascular, microbial and social factors leads to dysregulated and persistent inflammation (4). The current therapies for IBD rely highly on the use of immune suppressive drugs, including 5-aminosalicylic acid and corticosteroids (5). However, a number of patients either do not respond to these agents or demonstrate significant adverse effects (5). There is an urgent need to develop novel and effective anti-inflammatory substances with minimal side effects. Dietary flavonoids have been demonstrated to effectively and mildly regulate expression of inflammatory cytokines, alleviate the necrosis of colon tissue and relieve clinical symptoms in patients with IBD (6,7).

Kaempferol (3,5,7-trihydroxy-2-(4-hydroxyphenyl)-4H-1-benzopyran-4-one), a flavonoid widely distributed in fruits, vegetables and plant-based foods, has been reported to possess anti-inflammatory, anti-diabetic, anti-hypertensive, anti-depressant and anti-ulcerative properties by acting on various cellular pathways (8-10). A previous study demonstrated that kaempferol had the most effective anti-inflammatory activities among eight polyphenols in a lipopolysaccharide (LPS)-induced Raw 264.7 cell model (11). *In vivo* studies additionally suggested that

kaempferol exerts a distinct anti-inflammatory effect on dextran sulfate sodium-induced UC in mice (12). However, to the best of our knowledge, there are no studies at present that have focused on the role kaempferol serves in LPS-induced intestinal microvascular endothelial cells. Intestinal microvascular endothelial cells, the primary components of the intestinal capillaries, have been demonstrated to be one of the most important secretory and immune cells in the process of inflammation, which is closely associated with the occurrence and progression of IBD (12,13).

In order to further investigate the beneficial effect of kaempferol and the possible mechanisms involved in the intestinal inflammation process, LPS-stimulated rat intestinal microvascular endothelial cells (RIMVECs) were used to establish a cell model of IBD. It was demonstrated that kaempferol may alleviate LPS-induced inflammatory mediators, including TNF- α , IL-1 β , IL-6, ICAM-1 and vascular cell adhesion molecule-1 (VCAM-1), by suppressing the activation of toll-like receptor 4 (TLR4), signal transducer and activator of transcription (STAT) and nuclear factor- κ B (NF- κ B).

Materials and methods

Reagents and antibodies. Kaempferol (purity $\geq 98\%$) was purchased from the National Institutes for Food and Drug Control (Beijing, China). Kaempferol was dissolved in dimethyl sulfoxide (DMSO); the final concentration of DMSO was $<0.1\%$ (v/v) when kaempferol was added to the experimental cells. Cell culture reagents, namely Dulbecco's modified Eagle's medium (DMEM) and fetal bovine serum (FBS) were obtained from Gibco (Thermo Fisher Scientific, Inc., Waltham, MA, USA). Endothelial cell growth supplement (ECGS) was purchased from EMD Millipore (Billerica, MA, USA). LPS (*Escherichia coli* 055:B5) was provided by Sigma-Aldrich (Merck KGaA, Darmstadt, Germany). The Cell Counting Kit-8 (CCK-8) was purchased from Dojindo Molecular Technologies, Inc. (Kumamoto, Japan). Rat TNF- α (cat. no. DY510), IL-1 β (cat. no. DY501), IL-6 (cat. no. DY506), ICAM-1 (cat. no. DY583) and VCAM-1 (cat. no. DY809) ELISA kits were obtained from R&D Systems, Inc. (Minneapolis, MN, USA). Antibodies for TLR4 (cat. no. ab22048), phosphorylated (p)-inhibitor of κ B (I- κ B) (cat. no. ab133462) and p-NF- κ B p65 (cat. no. ab28856) were purchased from Abcam (Cambridge, UK). Antibodies for p-p38 (cat. no. 4511) mitogen-activated protein kinase (MAPK) and p-STAT (cat. no. 9145) were obtained from Cell Signaling Technology, Inc. (Danvers, MA, USA). The antibody against β -actin (cat. no. AC006) was purchased from ABclonal Biotech Co., Ltd. (Wuhan, China).

Cell culture and treatment. RIMVECs were isolated and cultured, as described previously (14,15). A total of six neonatal rats at 1-day-old (gender undetermined; weight, 5–8 g) were purchased from the Academy of the Military Medical Sciences (Beijing, China). The present study was approved by the China Agriculture University Institutional Animal Care and Use Committee (approval no. CAU20160031201). RIMVECs were maintained with DMEM containing 15% (v/v) FBS, 0.5% (w/v) ECGS, and 1% (v/v) penicillin-streptomycin mixed solution. All cells were incubated at 37°C in a humidified incubator with 5% CO₂. Cells were starved in serum-free medium for 12 h prior to each experiment.

Cell viability assay. Cell viability was measured with a CCK-8 assay. RIMVECs were seeded at a density of 1×10^4 cells/well in 96-well plates for 24 h. Subsequently, the cells were treated with 100 μ l of kaempferol at different concentrations (200, 100, 50, 25, 12.5 and 6.25 μ M) for 12 h. Following treatment, the medium was removed, and cells were cultured in 100 μ l fresh DMEM containing 10% CCK-8 solution at 37°C for 2 h. Cell viability was determined by measuring the absorbance with a microplate reader (Bio-Rad Laboratories, Inc., Hercules, CA, USA) at 450 nm.

Measurement of cytokines and adhesion protein. TNF- α , IL-1 β , IL-6, ICAM-1, and VCAM-1 protein expression levels in culture supernatant were measured by ELISA, according to the manufacturer's protocol. RIMVECs were seeded in 12-well plates (1×10^5 cells/well). At 90% confluency, the cells were washed with PBS prior to the addition of medium with different concentrations of kaempferol (50, 25 and 12.5 μ M). After 3 h, cells were washed once with PBS and subsequently stimulated with 10 μ g/ml LPS (1 ml/well) for 6 h (TNF- α , IL-1 β and IL-6) or 12 h (ICAM-1 and VCAM-1) prior to the collection of the supernatant and measurement of inflammatory factors.

Western blot analysis. At the end of the incubation period, cells were lysed in radioimmunoprecipitation lysis buffer (2% SDS; 10% glycerol; 62.5 mM Tris-HCl buffer; pH 6.8) on ice. Protein concentrations were determined using a bicinchoninic acid protein assay kit (Beyotime Institute of Biotechnology, Haimen, China). Samples with equal quantities of total protein (20 μ g) were loaded and separated by 10% SDS-PAGE and transferred to nitrocellulose membranes (Pierce; Thermo Fisher Scientific, Inc.). The membranes were blocked in 5% bovine serum albumin (Gibco; Thermo Fisher Scientific, Inc.) for 1 h at room temperature, and were immunoblotted with the specific primary antibodies against TLR4 (1:800), p-NF- κ B p65 (1:1,000), p-I- κ B (1:1,000), p-p38 (1:800), p-STAT (1:800) and β -actin (1:2,000) overnight at 4°C. Membranes were subsequently incubated with horseradish peroxidase-conjugated secondary antibody (1:10,000; Cell Signaling Technology, Inc.; cat. no. SC3901) for 1 h at room temperature. Subsequently, the blots were visualized with an enhanced chemiluminescence immunoblotting detection system (Beyotime Institute of Biotechnology) and quantified using ImageJ (v1.51; National Institutes of Health, Bethesda, MD, USA).

Statistical analysis. Data are expressed as mean \pm standard deviation, and analyzed by one-way analysis of variance followed by Student-Newman-Keuls test for multiple comparisons. All analyses were performed by GraphPad Prism 7 software (GraphPad Software Inc., La Jolla, CA, USA). $P < 0.05$ was considered to indicate a statistically significant difference.

Results

Viability of RIMVECs treated with kaempferol. The chemical structure of kaempferol is presented in Fig. 1A. The cytotoxicity of kaempferol was assessed using the CCK-8 assay. As demonstrated in Fig. 1B, a high concentration of kaempferol (200 μ M) significantly decreased cell viability ($P < 0.01$); whereas,

Figure 1. Effects of kaempferol on cell viability of rat intestinal microvascular endothelial cells. (A) Chemical structure of kaempferol. (B) Cells were incubated with different concentrations of kaempferol (200, 100, 50, 25, 12.5 and 6.25 μ M) for 12 h. Cell viability was determined by a Cell Counting Kit-8 assay. Data are presented as the mean \pm standard deviation. n=6. **P<0.01 vs. control cells. OD, optical density.

treatment with concentrations between 6.25 and 100 μ M kaempferol exhibited no effect on cell viability. These results suggest that kaempferol is non-cytotoxic to RIMVECs within the concentrations of 3.125 and 100 μ M. According to the results, concentrations of 12.5, 25 and 50 μ M kaempferol were selected for subsequent experimentation.

Kaempferol decreases TNF- α , IL-1 β and IL-6 upregulation induced by LPS. Pretreatment for 3 h with kaempferol at different concentrations (12.5, 25 and 50 μ M) was followed by treatment with LPS (10 μ g/ml) stimulation for 6 h. As presented in Fig. 2, LPS stimulation significantly increased the secretion of inflammatory mediators above basal expression levels (Fig. 2A, TNF- α , 2.61-fold; Fig. 2B, IL-1 β , 2.36-fold; Fig. 2C, IL-6, 4.25-fold; P<0.01). Pretreatment with kaempferol at all concentrations resulted in significant decreases in the concentrations of TNF- α , IL-1 β and IL-6 compared with the LPS-model group (P<0.01).

Kaempferol partially suppresses LPS-induced ICAM-1 and VCAM-1 overproduction. As presented in Fig. 3, LPS stimulation significantly increased the secretion of inflammatory mediators above the basal expression levels (Fig. 3A, ICAM-1, 2.04-fold; Fig. 3B, VCAM-1, 3.67-fold; P<0.01). Although no significant reduction in ICAM-1 and VCAM-1 secretion was observed in the 12.5 μ M kaempferol group, significant decreases in ICAM-1 and VCAM-1 concentration were observed in the 50 and 25 μ M kaempferol groups compared with the LPS-treated group (P<0.05).

Kaempferol inhibits LPS-induced NF- κ B p65 and I- κ B phosphorylation. The NF- κ B pathway serves a critical role in the secretion of cytokines (10). The anti-inflammatory effect of kaempferol may be associated with the prevention

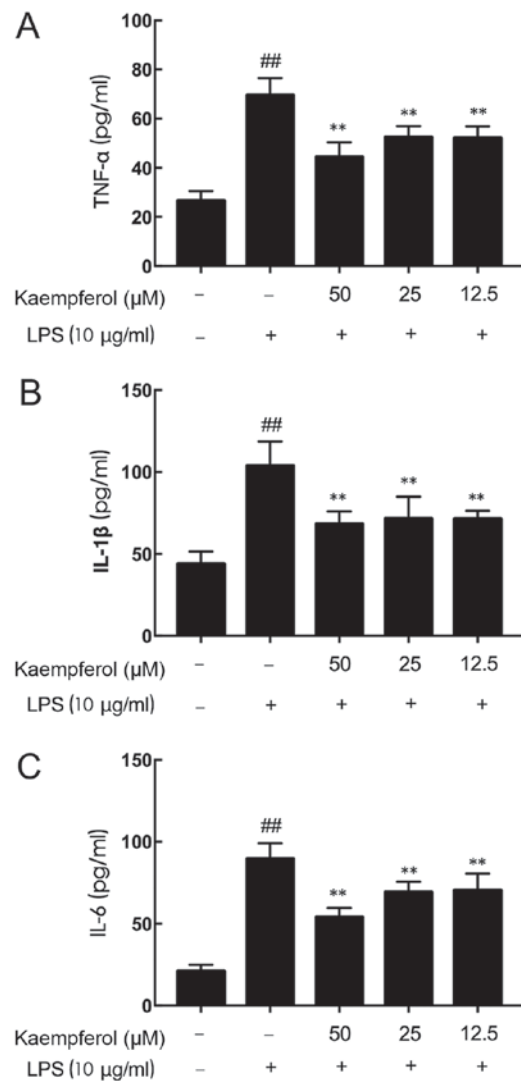

Figure 2. Kaempferol inhibits cytokine production induced by LPS in rat intestinal microvascular endothelial cells. Cells were treated with three different concentrations of kaempferol (50, 25 and 12.5 μ M) for 3 h and subsequently stimulated with LPS (10 μ g/ml). After 6 h, (A) TNF- α , (B) IL-1 β and (C) IL-6 protein secretion in the culture supernatant was quantified using an ELISA kit. Data are presented as the mean \pm standard deviation. n=4. ##P<0.01 vs. control cells; **P<0.01 vs. cells stimulated with LPS. LPS, lipopolysaccharide; TNF- α , tumor necrosis factor- α ; IL, interleukin.

of NF- κ B activation. As presented in Fig. 4, there was a significant increase in the phosphorylation of the p65 subunit (p-NF- κ B p65/NF- κ B p65 ratio) and I- κ B (p-I- κ B/I- κ B) in the model group compared with the control group (P<0.01). However, pretreatment with three different concentrations of kaempferol significantly decreased the LPS-induced increased p-NF- κ B p65/ β -actin ratio (P<0.01). As for I- κ B, although 12.5 and 25 μ M kaempferol was not able to decrease the phosphorylation of I- κ B induced by LPS, treatment with 50 μ M kaempferol significantly decreased the p-I- κ B level (P<0.01).

Kaempferol inhibits LPS-induced TLR4 overexpression. Activation of the TLR4 signaling pathway may directly lead to the activation of NF- κ B to regulate the production of cytokines (9,10). The present results demonstrated that LPS significantly upregulated TLR4 expression (Fig. 5; P<0.01). Pretreatment with different concentrations of kaempferol

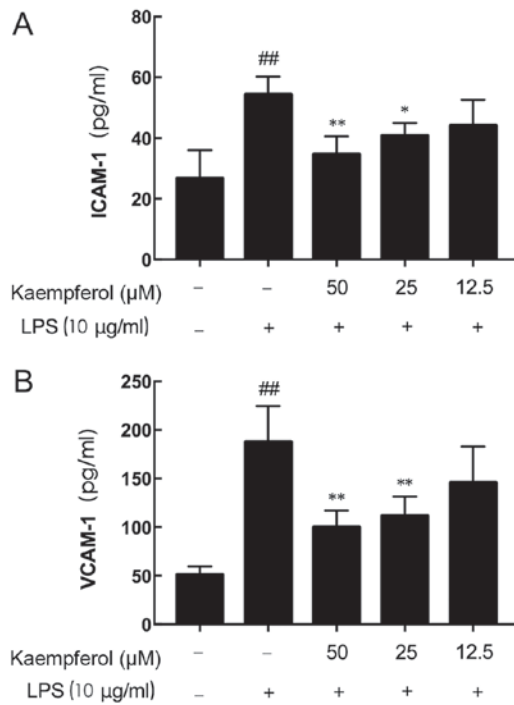

Figure 3. Kaempferol inhibits the production of adhesion protein induced by LPS in RIMVECs. RIMVECs were treated with three different concentrations of kaempferol (50, 25 and 12.5 μ M) for 3 h and subsequently stimulated with LPS (10 μ g/ml). After 12 h, (A) ICAM-1 and (B) VCAM-1 expression level in the culture supernatant was quantified with an ELISA kit. Data from individual experiments are presented as the mean \pm standard deviation. n=4. ^{##}P<0.01 vs. control cells; ^{*}P<0.05, ^{**}P<0.01 vs. cells stimulated with LPS. RIMVECs, rat intestinal microvascular endothelial cells; ICAM-1, intercellular adhesion molecule 1; LPS, lipopolysaccharide; VCAM-1, vascular cell adhesion molecule 1.

significantly inhibited the LPS-induced overexpression of TLR4 (Fig. 5; P<0.01).

Kaempferol does not affect LPS-induced p38 MAPK phosphorylation. The p38 MAPK signaling pathway additionally serves an important role in inflammatory response. In response to LPS, the level of p-p38 was significantly upregulated in the model group compared with the control group (Fig. 6; P<0.01). Compared with the model group, kaempferol at 50 μ M did not affect the expression level of p-p38.

Kaempferol inhibits LPS-induced STAT phosphorylation. The STAT pathway is another important inflammatory signaling pathway. As demonstrated in Fig. 7, cells subjected to LPS exhibited significantly increased STAT phosphorylation compared with the control group (P<0.01). By contrast, significant downregulation STAT phosphorylation was observed in the 50 μ M kaempferol treatment group compared with the model group (P<0.01).

Discussion

IBD is a chronic inflammatory disease of intestinal mucosa and submucosa, characterized by disruption of the intestinal epithelial barrier, increased production of inflammatory mediators and excessive tissue injury (16). Intestinal microvascular endothelial cells, the primary components of intestinal

Figure 4. Kaempferol inhibits activation of NF- κ B induced by LPS in rat intestinal microvascular endothelial cells. Cells were treated with various concentrations (50, 25 and 12.5 μ M) of kaempferol for 3 h followed by treatment with LPS (10 μ g/ml). (A) After 3 h, p-NF- κ B p65, NF- κ B p65, p-I- κ B and I- κ B protein expression levels were analyzed by western blotting. (B) p-NF- κ B p65/NF- κ B and (C) p-I- κ B/I- κ B ratios were determined by densitometry. capillaries, have been demonstrated to be one of the most important secretory and immune cells in IBD (13). Intestinal microvascular endothelial cells produce and respond to inflammatory mediators (17,18). As demonstrated in previous studies, in response to LPS stimulation, RIMVECs express the inflammatory cytokines, TNF- α , IL-1 β and IL-6, the chemokine IL-8, the adhesion molecule ICAM-1 and other inflammatory mediators, including nitric oxide and endothelin-1 (14,19,20). Considering that LPS is a principal pro-inflammatory factor in the progression of IBD (21), LPS-stimulated RIMVECs were selected as a cellular model of intestinal inflammation.

Inflammatory mediators, including cytokines, adhesion proteins and chemokines, have an important role in

IL-1 β , IL-6, adhesion molecules and pro-coagulant factors (17). Furthermore, TNF- α is an initiation factor of acute immune responses, cytotoxicity and apoptosis, but can also inhibit apoptosis (2,22). In the present study, it was demonstrated that kaempferol was able to protect RIMVECs from LPS-induced overexpression of three inflammatory mediators, TNF- α , IL-1 β and IL-6. Therefore, the results of the present suggested that the inhibition of inflammatory cytokines may contribute to the protective effects of kaempferol in IBD.

In IBD, activation of microvascular endothelial cells and adhesion of circulating immune cells is required for the initiation and maintenance of inflammation (23). Pro-inflammatory cytokines, including TNF- α and IL-1 β , induce inflammatory responses in the vascular endothelium, which results in enhanced expression of cell adhesion molecules, including ICAM-1 and VCAM-1 (2). Overexpression of adhesion molecules in the intestinal endothelium may promote recruitment and adhesion of leukocytes, promoting the process of inflammatory response (9,24). In the present study, the beneficial effect of kaempferol was demonstrated in the altered production of ICAM-1 and VCAM-1. The overexpression of ICAM-1 and VCAM-1 is involved in inflammatory processes; however, are additionally closely associated with intestinal carcinogenesis, secondary to IBD (17,25). Therefore, the present results suggest that kaempferol may effectively reduce the expression of inflammatory mediators, against intestinal inflammation, and may reduce the risk of carcinogenesis in patients with IBD.

NF- κ B has an essential role in regulating the expression of inflammatory cytokines and adhesion molecules (26). Due

to the pivotal role of NF- κ B in inflammation, the blockade of NF- κ B activity is considered to be associated with inhibition of the inflammatory signaling cascade (27,28). Inhibition of NF- κ B activation is an effective strategy for preventing the progression of IBD in experimental animal models and preventing inflammatory cytokine production in patients with IBD (29). Under basal conditions, NF- κ B is sequestered in the cytoplasm by a family of inhibitory proteins known as inhibitors of NF- κ B (I- κ Bs). Following stimulation with LPS, NF- κ B is activated, triggering expression of a series of inflammatory cytokine (28). In the present study, LPS increased the phosphorylation of NF- κ B p65 and I- κ B, which effectively indicates the activation level of NF- κ B. However, kaempferol significantly reduced the LPS-induced activation of NF- κ B, suggesting that the anti-inflammatory activities of kaempferol were due to the inhibitory effect on NF- κ B. The present study suggested a direct role of kaempferol in the prevention of LPS-stimulated NF- κ B activation in RIMVECs.

TLRs are pattern recognition receptors that 'sense' microbes and alert the immune system through activation of transcription factors (including NF- κ B) and the secretion of inflammatory mediators (9). TLR4 is the specific ligand of LPS, serving an important role in inflammatory disease, including IBD. Activation of TLR4 may lead to phosphorylation of MAPKs, I- κ B kinases and NF- κ B, eventually contributing to the expression of pro-inflammatory cytokines (30,31). Compared with the significantly increased expression of TLR4 in LPS-treated RIMVECs, the administration of kaempferol significantly reduces the TLR4 expression in LPS-treated cells. This suggests that kaempferol may represent a novel strategy to limit the TLR4-mediated inflammatory process.

The MAPK signaling pathways, including extracellular signal-regulated kinase 1 and 2, c-jun N-terminal kinase and p38, are closely associated with the expression of inflammatory mediators and oxidative damage (32). Previous studies demonstrated that MAPKs are highly activated and mediate pro-inflammatory cytokines, including TNF- α , IL-1 β and IL-6 in the colon tissue of an IBD mice model and patients with IBD (33,34). Kaempferol was demonstrated to suppress the expression of the LPS-induced MAPK pathway in the human monocytic cell line THP-1 (35), in addition to suppressing the production of cyclooxygenase-2 (COX-2), prostaglandin E2 and matrix metalloproteinases (MMPs) via MAPK in IL-1 β -induced rheumatoid arthritis synovial fibroblasts (36). Additionally, kaempferol treatment of the human synovial sarcoma cell line, SW982 cells, significantly inhibited IL-1 β -induced p38 MAPK phosphorylation, which were involved in the production of IL-6, IL-8, MMP and COX-2 (37). However, the role of kaempferol in IBD-associated cells has rarely been studied. In the present study, it was identified that kaempferol did not demonstrate any detectable influence on the phosphorylation of p38 in LPS-stimulated RIMVECs. The present results suggest that the anti-inflammatory effect of kaempferol is not dependent on the p38 MAPK pathway.

The STAT pathway is another crucial signaling cascade involved in IBD. It is well documented that the STAT pathway is not only associated with the inflammatory process in IBD; however, is additionally associated with further serious conditions, including colorectal cancer development (38,39). Recent

studies demonstrated that luteolin, a naturally occurring flavonoid, inhibited the Janus kinase (JAK)/STAT pathway in cytokine-induced HT-29 cells, a human epithelial cell line (39). Curcumin, a natural phenol, suppressed inflammation of TNBS-induced colitis in mice via STAT signaling (40). Although it was demonstrated that kaempferol attenuates inflammation by suppressing the STAT pathway in human airway epithelial cells (41), to the best of our knowledge, no study has focused on the effect of kaempferol on the JAK/STAT pathway in IBD-associated cells. The results of the present suggest that STAT may be associated with the suppressive effects of kaempferol against the production of inflammatory mediators in LPS-stimulated RIMVECs.

In conclusion, it was demonstrated that kaempferol significantly inhibits the LPS-induced expression of the inflammatory mediators TNF- α , IL-1 β , IL-6, ICAM-1 and VCAM-1 by inhibiting TLR4, NF- κ B and STAT signaling, but not by activating p38 MAPK signaling in RIMVECs. The present results provide novel insight for the inflammatory effect of kaempferol in endothelial cells. It suggests that kaempferol may be an effective therapeutic agent for treatment of IBD, and that fruits and herbs rich in kaempferol may be incorporated into potential health care products for patients with IBD.
