Abstract. Prednisolone is an anti-inflammatory drug used to treat a number of conditions, including liver disease and cancer. Numerous studies have demonstrated that glucocorticoids such as prednisolone modified by ionizing radiation can promote anticancer activity in cancer cells. To the best of our knowledge, however, the effect of ionizing radiation on prednisolone structure and cancer cells has not yet been identified. The present study created a novel prednisolone derivative using γ -irradiation, and its anticancer properties were investigated in liver cancer cells. The present study confirmed the structure of the new prednisolone derivative using liquid chromatogram-mass spectrometry. MTT assays determined the cytotoxic effects of γ -irradiated (IR)-prednisolone in liver cancer cells. Flow cytometry analysis evaluated apoptosis, mitochondrial membrane potential and cell cycle distribution. Western blotting was used to analyze the proteins associated with apoptosis. The chromatogram profile revealed that IR-prednisolone produced a number of peaks compared with the single peak of the original prednisolone. In contrast to prednisolone, the MTT results showed that IR-prednisolone significantly prevented the growth of liver cancer cells. IR-prednisolone promoted apoptosis and arrested the cell cycle at the G0/G1 stage in Huh7 cells. IR-prednisolone also altered the mitochondrial membrane potential and activated caspase-associated proteins, which activated the intrinsic

apoptotic signaling pathway. In conclusion, IR-prednisolone promoted anticancer effects in liver cancer cells via apoptosis activation. The present study demonstrated that IR-prednisolone may be a potential anticancer agent against liver cancer, although specific molecules have yet to be identified.

Introduction

Glucocorticoids (GCs) are anti-inflammatory and immunosuppressant agents that have been studied as potential treatments for hematological cancer (1). GCs are also used as drug adjuvants for the prevention and amelioration of non-hematological cancer (2,3). Mechanistically, GCs exert antitumor effects by inducing apoptosis, inhibiting cell proliferation and modulating the inflammatory pathway (4,5). Prednisolone is a commonly used GC for treating liver disease and cancer (6,7). Previous studies have demonstrated that prednisolone increases apoptosis in CCRF-CEM cells (8,9). Prednisolone has also been reported to enhance the metabolism of sorafenib, which can improve the outcome of therapy in the treatment of hepatocellular carcinoma (10). However, GC has anti-cancer effects in haematologic malignancies, but it has limited effects in solid tumors (11,12). Therefore, the development of novel drug derivatives may have notable implications for improving the efficacy for GC-based cancer treatment.

Ionizing radiation is used to modify the structure of numerous drugs, and has been demonstrated to enhance their biological properties *in vitro* (13,14). Recent reports have demonstrated that γ -irradiation can create novel GC derivatives, such as γ -irradiated (IR)-dexamethasone (Dex-IR) and Kenalog-IR, the anticancer effects of which have been confirmed *in vitro* (15,16). To the best of our knowledge, however, the effects of γ -irradiation on prednisolone structure, and the mechanism by which it induces anticancer effects, have not yet been explained.

In order to determine the biological activities of new prednisolone derivatives created using γ -irradiation, the present study evaluated the anticancer activities of IR-prednisolone in liver cancer cells. The present study demonstrated that

Key words: apoptosis pathways, ionizing radiation, γ -irradiated glucocorticoids, Huh7 cells, prednisolone

IR-prednisolone decreased the growth of Huh7 and HepG2 cells. Thus, it was hypothesized that IR-prednisolone may have anticancer properties in liver cancer cells.

Materials and methods

Cell lines, chemicals and reagents. Huh7 and HepG2 cells were acquired from the American Type Culture Collection. The cells were maintained in DMEM containing 10% fetal bovine serum and 1% streptomycin/penicillin (all from Thermo Fisher Scientific, Inc.) at 37°C in a humidified 5% CO₂ incubator. Prednisolone, MTT and doxorubicin were obtained from Sigma-Aldrich (Merck KGaA). The Muse[®] Annexin V Dead cell kit and cell cycle arrest package for flow cytometry analysis, and the PVDF membranes were purchased from EMD Millipore. For nick-end labeling, the DeadEnd[™] Fluorometric TUNEL System was purchased from Promega Corporation. The human apoptosis proteome array kit was obtained from Bio-Rad Laboratories, Inc. The ECL detection reagent was bought from GE Healthcare. RIPA buffer was procured from Rockland Immunochemicals, Inc. Bicinchoninic acid (BCA) reagent was obtained from Thermo Fisher Scientific, Inc. The cytochrome c release kit (cat. no. ab65311) was from Abcam. Anti-GAPDH, anti-cleaved caspase 3, anti-cleaved caspase 9, anti-caspase 9, anti-cleaved poly-ADP ribose polymerase (PARP), anti-PARP, anti-caspase 3, anti-Bcl-2, anti-Bax, and horseradish peroxidase (HRP)-conjugated anti-rabbit IgG and anti-mouse (cat. nos. 2118, 9664, 9505, 9502, 9541, 9532, 9662, 2870, 5023, 7074 and 7076, respectively) were obtained from Cell Signaling Technology, Inc.

Prednisolone modification using γ -irradiation. Prednisolone was modified using γ -irradiation under the conditions described by Lee *et al.* (15). Liquid chromatography-mass spectrometry (LC-MS) analysis was used to determine the structural changes in IR-prednisolone. Briefly, a sample solution of prednisolone (1 g) in MeOH (1 liter) in capped vials was exposed to 50 kGy (absorbed dose) of radiation. Irradiation was carried out at ambient temperature using a Cobalt-60 irradiator [Nordion (Canada), Inc.] at the Advanced Radiation Technology Institute, Korea Atomic Energy Research Institute (Jeongup, Korea). The source strength was ~320 kCi, with a dose rate at the location of the 10 kGy/h sample. The prednisolone and IR-prednisolone samples were assessed using the HPLC 1260 system (Agilent Technologies, Inc.) on a YMC-Pack ODS-A 302 column (4.6x150 mm; YMC Co., Ltd.). It was developed at 40°C with 1% HCOOH/MeCN (1:1, flow rate, 1.0 per min; detection, 360 nm). LC-MS was performed using an Agilent 1100 series LC-MSD system (Agilent Technologies, Inc.) in both positive and negative ion modes. Separation was performed with a YMC-Pack Pro C18 reverse-phase column (250x4.6 mm² I.D. S-5 μ m, 12 nm; YMC Co., Ltd.) at a flow rate of 1 ml/min. The mobile phase consisted of 0.1% (v/v) trifluoroacetic acid (TFA; solution A) and 50% (v/v) acetonitrile in 0.1% (v/v) TFA (solution B). Elution was performed by a step gradient from a ratio of 80:20 (solutions A:B) to 67:33 in 18 min; from 67:33 to 60:40 in 12 min; and then from 60:40 to 80:20 in 10 min. The eluted compounds were detected at a wavelength

of 520 nm. Electrospray ionization was performed with an ES-APCI mass spectrometer (Agilent Technologies, Inc.). Hydrogen was used as the nebulizing and drying gas. The ESI conditions used were as follows: Nebulizer pressure, 35 psig; drying gas, 12 l/min at 350 °C; ion spray voltage, 4,000 V; and charging voltage, 2,000 V.

MTT cell viability assay. Huh7 and HepG2 cells were grown for 24 h and treated with prednisolone or IR-prednisolone (5, 10, 50 and 100 μ g/ml), or DMSO as negative control for 48 h at 37°C. Following incubation, 20 μ l MTT mixture was added for 2 h at 37°C. The medium was replaced by 100 μ l DMSO to break down formazan precipitates. The absorbances were measured at 562 nm using an Infinite M200 multimode microplate reader (Tecan Group, Ltd.).

Propidium iodide (PI) staining for cell cycle detection. Huh7 cells were grown for 24 h before being stimulated with 100 μ g/ml prednisolone or IR-prednisolone, or 0.5 μ M doxorubicin as a positive control, for a further 24 h. Cells were fixed in 70% ethanol at -20°C for 3 h, then stained with 150 μ l PI at 25°C for 30 min in the absence of light. The Muse Cell Analyzer (EMD Millipore) estimated the number of stained nuclei.

Annexin V-FITC/PI staining for apoptosis assay. Annexin V-FITC/PI staining determined the number of cells in each population. Huh7 cells were cultured for 24 h. The cells were treated as described in the cell cycle assay. Then cells were harvested, and stained with 100 μ l Annexin V-FITC/PI solution at room temperature for 20 min in the dark, as per the manufacturer's directions. The number of apoptotic cells was determined using the Muse Cell Analyzer (EMD Millipore). The Muse software (version 1.1.2; EMD Millipore) evaluated the numbers of apoptotic and non-apoptotic cells in each of the four populations: Live cell; Annexin V (-) and PI (-); early apoptotic cell; Annexin V (+) and PI (-), late apoptotic or dead cell; Annexin V (+) and PI (+); and dead non-apoptotic cell; Annexin V (-) and PI (+).

TUNEL assay. Huh7 cells were grown on microscope slides for 24 h. The treatment conditions used for apoptosis analysis were applied for 12 h, then cells were analysed using the TUNEL assay kit (Promega Corporation) and counterstained using DAPI according to the supplier's instructions. In brief, the cells were washed with cold PBS, fixed with 4% paraformaldehyde for 20 min at room temperature. Subsequently, the cells were permeabilized by immersing the slide in 0.2% Triton X-100 solution in PBS for 5 min. The cells were washed again in cold PBS twice for 2 min. The equilibration buffer was added for 10 min at room temperature, followed by 100 μ l terminal deoxynucleotidyl transferase (TdT) reaction mix, covered and incubated at 25°C for 60 min. The slides were then immersed in 2X saline sodium citrate for 15 min to terminate the reaction and washed three times for 5 min each in PBS to remove unbound biotinylated nucleotides. The nuclei were stained with DAPI and incubated at room temperature for 5 min. After mounting, the apoptotic cells were captured on an Olympus IX71 fluorescence microscope (magnification, x40; Olympus Corporation). To

quantify the immune-probed cells, the fluorescence intensity was taken in 10 randomly selected images.

Human apoptosis array assessment. Huh7 cells were grown on a 100-mm plate for 24 h, following treatment with 100 $\mu\text{g/ml}$ IR-prednisolone or DMSO for 24 h. Briefly, harvested cells were lysed with 1X RIPA buffer (Rockland Immunochemicals, Inc.), and concentrations were calculated using the BCA protein assay. Then, 250 μg total proteins were incubated in the nitrocellulose membrane (NC) overnight at 4°C. The assay was performed using the apoptosis proteome array kit following the manufacturer's instructions; subsequently, NC membranes were developed on X-ray film for 5 min. Each protein was estimated using Multi Gauge software (version 3.0; FujiFilm).

Western blotting analysis. Huh7 cells (9×10^5 cells/plate) were grown in a 100-mm plate for 24 h. The treatment conditions (for 12 and 24 h) were the same as for cell cycle analysis. Protein extraction was performed using RIPA buffer and, the cytochrome c release kit was used to isolate cytosol and mitochondria fractions. Protein concentrations were determined using the BCA protein assay. Equal volumes of 40 μg proteins were separated via SDS-PAGE on 10% gels, and then transferred onto PVDF membranes and blocked in non-fat milk in tris-buffered saline with 0.1% Tween-20 (TBST) buffer at room temperature. The membranes were incubated overnight with primary antibodies (1:1,000) and cytochrome c antibody (1:500) at 4°C, then washed with three changes of TBST buffer. The membranes were incubated with anti-rabbit conjugated-HRP (1:3,000) and anti-mouse conjugated-HRP (1:3,000) at room temperature for 1 h, followed by three washes in TBST. The proteins were then visualised using an enhanced chemiluminescence reagent (ECL; EMD Millipore) and exposure to an X-ray film. The blots were scanned and densitometric analysis was performed using ImageJ software (version 1.51k; National Institutes of Health).

JC-1 staining for determination of mitochondrial membrane potential ($\Delta\Psi\text{m}$). The double-emission fluorescence dye JC-1 was used to analyse the status of $\Delta\Psi\text{m}$. Huh7 cells (5×10^4) were grown for 24 h then treated with the aforementioned conditions for 48 h or with 50 μM carbonyl cyanide 3-chlorophenyl hydrazine (CCCP) for 30 min. Cells were stained with 1 ml DMEM containing JC-1 dye at 37°C for 20 min, then washed with two changes of PBS and reconstituted in PBS. For positive control cells, CCCP at 50 μM for 5 min was used to alter the $\Delta\Psi\text{m}$. JC-1-positive cells were detected using a Cytomics FC500 flow cytometer (Beckman Coulter, Inc.), whereas the red to the green fluorescent cell population was determined using CPX software version 2.2 (Beckman Coulter, Inc.).

Statistical analysis. The data are presented as the mean \pm standard deviation of ≥ 3 independent experiments. Statistical analysis was performed using Student's t-test and PASW Statistics software version 18 (SPSS, Inc.). Multiple comparisons were performed using one-way ANOVA then Tukey's post hoc analysis. $P < 0.05$ was considered to indicate a statistically significant difference.

Results

Effects of γ -irradiation on prednisolone structure. The results of the present study demonstrated that the prednisolone chromatogram had a single peak at the retention time of 19.625 min with a mass of 361.4 m/z (Fig. 1A). The IR-prednisolone chromatogram showed five new daughter peaks detected at retention times of 17.241, 17.397, 22.251, 23.633 and 30.957 min with masses of 392.9, 393.0, 355.0, 434.8 and 816.6 m/z respectively, whereas the mother peak of prednisolone had completely disappeared (Fig. 1B) indicating that 50 kGy γ -irradiation was able to generate new prednisolone derivatives.

IR-prednisolone prevents the growth of liver cancer cells. MTT assays were conducted to determine the anticancer effects of IR-prednisolone on liver cancer cell lines. IR-prednisolone significantly decreased the viability of Huh7 cells from 83.9% with prednisolone to 47.4% with IR-prednisolone at 100 $\mu\text{g/ml}$ (Fig. 2A). A significant decrease in cell viability was observed in HepG2 cells from 120% with prednisolone to 67% with IR-prednisolone at 100 $\mu\text{g/ml}$ (Fig. 2B). In contrast with the control group, IR-prednisolone decreased the cell viability of Huh7 cells by 52.6%, whereas the viability of HepG2 cells decreased by 33%. This indicated that IR-prednisolone was more sensitive to Huh7 cells than to HepG2 cells. Therefore, this cell line was used to investigate the anticancer effects of IR-prednisolone. In order to determine whether IR-prednisolone decreases cell viability by preventing cell cycle progression in Huh7 cells, the present study investigated the DNA content of cells in different phases of the cell cycle. The results of cell DNA content profiles demonstrated a significant increase in the number of cells at G0/G1 from 62.1% with prednisolone to 68.7% with IR-prednisolone. The slightly increased number of cells in the G0/G1-phase indicates that IR-prednisolone may induce cell cycle arrest in Huh7 cells (Fig. 2C and D). These results indicated that IR-prednisolone may prevent the growth of Huh7 cells.

IR-prednisolone increases the apoptosis of Huh7 cells. In order to determine the role of IR-prednisolone in inhibition of cell viability, programmed cell death was evaluated in Huh7 cells. The results of the present study demonstrated that IR-prednisolone significantly increased the population of total apoptotic cells to 36.3% compared with 11.3% in prednisolone-treated cells (Fig. 3A and B). In order to further confirm whether IR-prednisolone induced apoptosis, a TUNEL assay was performed. The results demonstrated that IR-prednisolone-treated cells displayed colocalization of TUNEL staining, which stains small fragments of DNA (green), and DAPI (blue), a nucleus and DNA staining dye, compared with prednisolone-treated cells, where no colocalization was observed (Fig. 3C). These results showed that prednisolone transformed through ionizing radiation effectively inhibit the viability of Huh7 cells by inducing certain physiological changes.

IR-prednisolone induces intrinsic apoptosis in Huh7 cells. In order to identify the mechanism of IR-prednisolone-induced

apoptosis, apoptosis-associated proteins were screened using western blotting. The apoptosis array results demonstrated that IR-prednisolone increased levels of cleaved caspase-3, Bax, tumor necrosis factor receptor 1, heme oxygenase-1, p21, phosphorylated-Rad17 and hypoxia inducible factor-1 α , but decreased the expression levels of cellular inhibitor of apoptosis-1, Claspin, Survivin, Bcl-2, Bcl-x and p27 (Fig. 4A). Furthermore, investigation of different proteins connected to apoptosis pathways revealed that IR-prednisolone treatment activated cleaved caspases 9 and 3, and increased cleaved PARP levels compared with those in prednisolone-treated cells in a time-dependent manner (Fig. 4B). These data demonstrated that IR-prednisolone activates the intrinsic apoptosis pathway.

Effect of IR-prednisolone on $\Delta\Psi_m$. Alteration of $\Delta\Psi_m$ is a critical process in the intrinsic apoptosis pathway (17). Therefore, involvement of intrinsic apoptosis was investigated by JC-1 staining. The results of depolarization status of $\Delta\Psi_m$ demonstrated that IR-prednisolone-treated cells increased JC-1 monomers (green fluorescence) up to 30.0% compared with 5.6% observed in prednisolone-treated cells (Fig. 5A). The Bcl-2 family of proteins is known to be a regulator of mitochondrial membrane dysfunction (18). Investigation of mitochondrial membrane dysfunction regulator proteins demonstrated that IR-prednisolone upregulated Bax and decreased levels of Bcl-2 compared with those in prednisolone-treated cells (Fig. 5B). The loss of $\Delta\Psi_m$ has been demonstrated to increase the total amount of cytochrome c movement towards the cytosol and

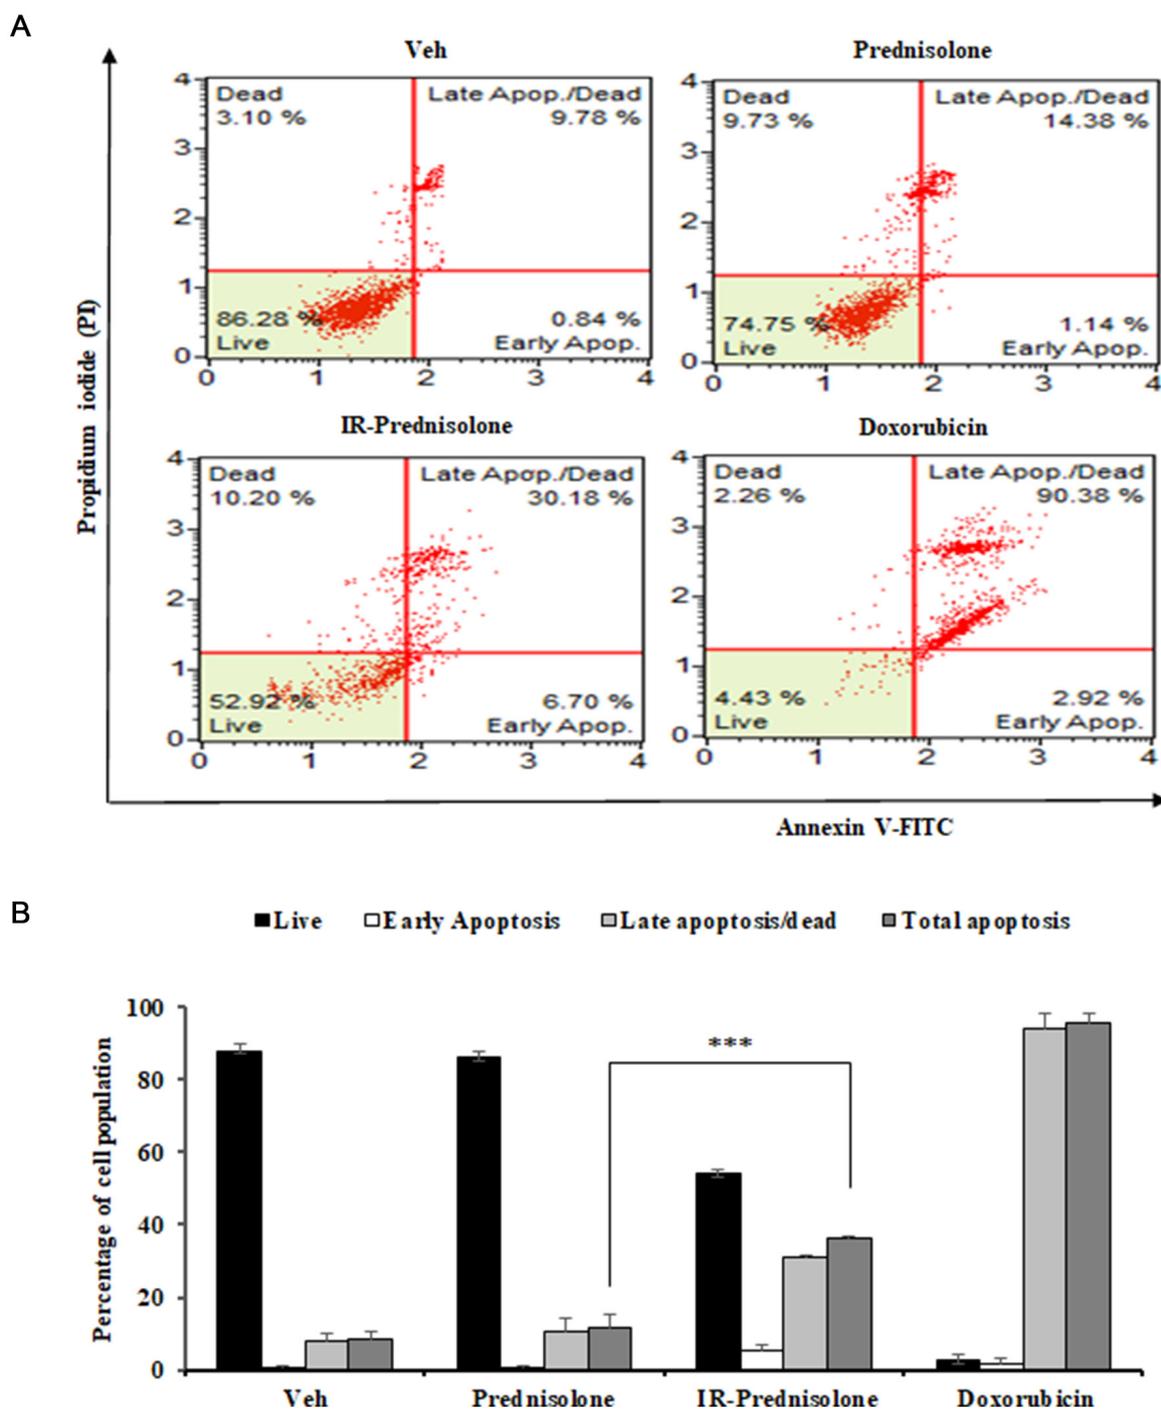

Figure 3. Continued.

mediate apoptosis signaling (19). The present study demonstrated that IR-prednisolone significantly increased cytosolic cytochrome c levels and decreased the level of mitochondrial cytochrome c in Huh7 cells (Fig. 5C and D), indicating that IR-prednisolone induced the intrinsic apoptosis signaling cascade.

Discussion

Prednisolone has been reported to exert anticancer actions in a number of cancer cells, including leukemia, and prostate and oesophageal cancers (20-22). Previous studies

have demonstrated that prednisolone increases the level of cytochrome P450 3A4, induces metabolism of sorafenib and enhances the efficacy of chemotherapy during treatment of patients with liver cancer (10). Although prednisolone shows therapeutic roles in numerous types of cancer, the extent of its efficacy remains debatable. In the present study, the structure of prednisolone was improved using γ -irradiation. Higher levels of cytotoxic effects were observed following treatment with IR-prednisolone compared with those in prednisolone-treated liver cancer cells. Therefore, it was hypothesized that IR-prednisolone may have anticancer activity in liver cancer cells.

The present study demonstrated that the use of ionizing radiation was a potential promising technique for structural modification. A number of studies have demonstrated that γ -irradiation modifies the structures of existing compounds in order to develop novel compounds (14,23,24). Lee *et al* (15) reported that GCs exposed to IR exhibit improved physiological properties. These studies have demonstrated that ionizing radiation can be used to improve the anticancer activity of drugs. The results presented in Fig. 1 are consistent with previous reports that IR-prednisolone drugs produce several peaks compared to the single peak of prednisolone (15,25). These observations indicate that γ -irradiation may be used to develop new prednisolone derivatives. The chemical structure

for IR-prednisolone was not determined in the present study; however, based on previous observations, it was hypothesized that γ -irradiation changes the arrangement of functional groups to produce new prednisolone derivatives (14,25).

The potential biological activity of IR-prednisolone was investigated using cancer cells. Among the tested cells (SK-MEL-5 as the skin cancer cell line, MCF7 as the breast cancer cell line and A549 as the lung cancer cell line), IR-prednisolone reduced cell viability only in the liver cancer cell lines, Huh7 and HepG2 (data not shown). Previous reports have demonstrated that γ -irradiated drugs promote anticancer activity primarily by decreasing cell proliferation and apoptosis induction (15,25). In the present study, IR-prednisolone

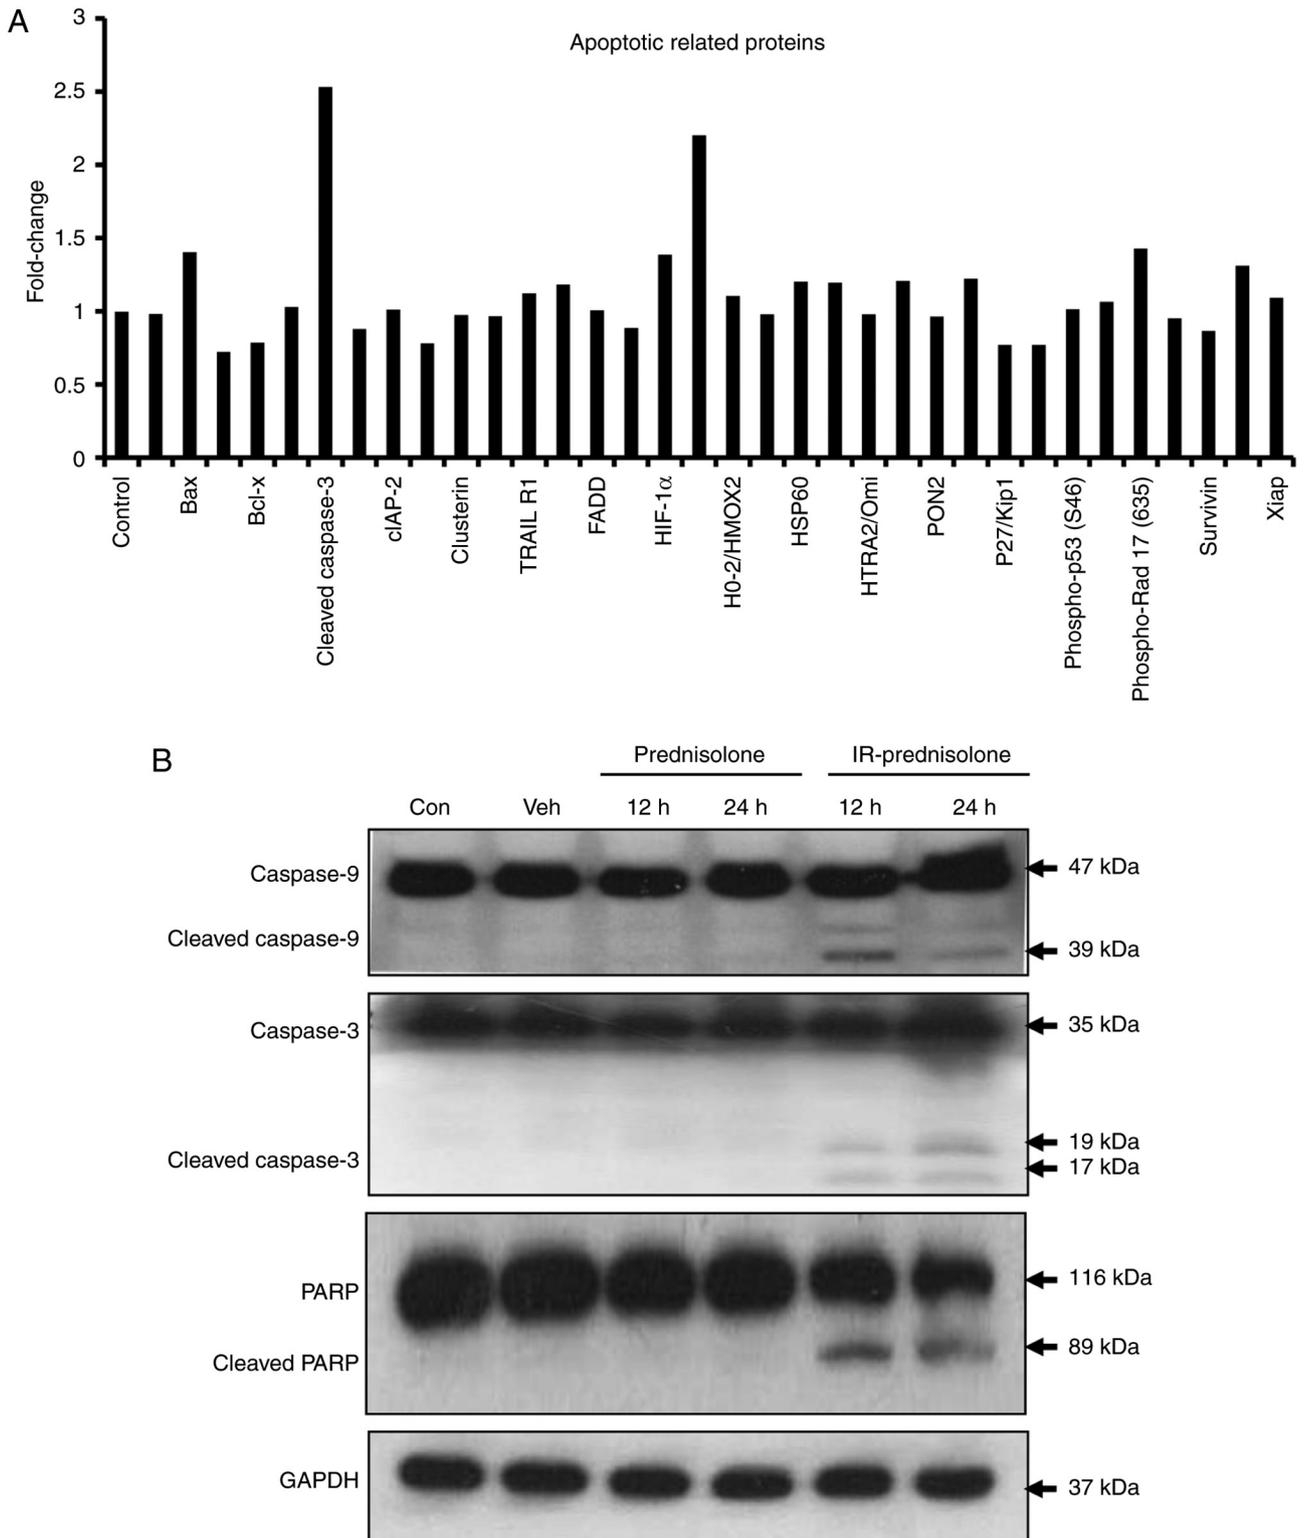

Figure 4. IR-prednisolone induces activation of proteins associated to apoptosis. (A) Bar graph of human apoptosis profile for apoptosis-associated proteins. (B) Western blotting of caspases associated with apoptotic pathways. GAPDH was used as the loading control. IR-prednisolone, γ -irradiated prednisolone; Veh, vehicle; PARP, poly-ADP ribose polymerase.

significantly decreased the viability of liver cancer cells. As the percentage of apoptotic cells has been demonstrated to increase in numerous types of cancer cell following treatment with γ -irradiated drugs, it was hypothesized that IR-prednisolone may decrease the viability of liver cancer cells by promoting apoptosis and cell arrest (16). Evading apoptosis is a hallmark

of cancer; potential anticancer drugs should therefore promote apoptosis (17). In the present study, apoptosis was accelerated in IR-prednisolone-treated Huh7 cells. DNA fragmentation is considered to be a hallmark of apoptosis, and is controlled by both endonucleases and caspases to form small fragments of DNA (17). DNA fragmentation demonstrated that

IR-prednisolone induced apoptosis by a mechanism similar to that reported in other studies (26-28). IR-prednisolone-treated cells were shown to be arrested at G₀/G₁, and similar results have been observed following treatment with Dex-IR (15).

The activation of caspases (aspartate-specific cysteine proteases) controls apoptosis (29). Also, Bcl-2/Bax play an important role in regulating caspase-dependent and caspase-independent apoptosis mediated by the mitochondrial pathway (19). The intrinsic apoptosis pathway is activated by Bax attached to mitochondria, following cytochrome c movement towards the cytosol, and activation of cleavage of caspase 9, caspase 3 and PARP (30). These events were observed in IR-prednisolone-treated cells, indicating that the intrinsic pathway was involved in IR-prednisolone-induced apoptosis (Fig. 6). Collectively, these findings indicate that IR-prednisolone increased apoptosis by activating the intrinsic apoptosis pathway.

Although the present study demonstrated the anticancer effects of IR-prednisolone, further analysis is required to identify the chemical structure and compounds within the IR-prednisolone mixture. In addition, separating individual fractions to analyse key single compounds and confirm their effectiveness will have to be carried out. Afterward, further research is required to investigate the molecular mechanism underlying these effects.

In conclusion, the present study demonstrated that γ -irradiation created a new prednisolone derivative. The results of the present study demonstrated that IR-prednisolone prevented the growth of liver cancer cells and arrested cells at the G₀/G₁ stage of the cell cycle. IR-prednisolone promoted apoptosis of Huh7 cells via alteration of $\Delta\Psi_m$, DNA fragmentation and decreased Bcl-2 expression levels. Mechanistically, IR-prednisolone activates the intrinsic apoptotic signaling pathway via caspase-dependent activation. However, further research is necessary to identify the specific molecules and mechanisms involved in this effect. The results of the present study indicate that IR-prednisolone obtained through radiolytic transformation technology is a potential candidate for the development of novel therapies for liver cancer.
