DOI: 10.3892/ol.2017.6179

**Abstract.** MicroRNAs serve important roles in various diseases, particularly cancer. microRNA-106a (miR-106a) exhibits abnormal expression and oncogenic activity in carcinogenesis. The clinical significance of the abnormal expression of miR-106a in colorectal cancer is poorly understood. In the present study, miR-106a expression from colorectal cancer tissues was quantified using the reverse transcription-quantitative polymerase chain reaction. The overexpression or knockdown of miR-106a was performed by transfection with microRNA mimic or inhibitor in human colorectal carcinoma HCT116 cells. The overexpression of miR-106a promoted viability and inhibited apoptosis in colorectal cancer cells. The association between miR-106a expression and clinicopathological factors was analyzed, and it was identified that miR-106a exhibited significantly increased expression in adenocarcinoma tissues compared with in mucinous carcinoma tissues, and the expression of miR-106a was identified to be associated with the depth of invasion and differentiation. The expression of miR-106a in plasma was also determined and it was identified that increased expression of miR-106a, as a characteristic of patients with colorectal cancer, may be distinguished from that of other patients by digitization of the areas under the receiver operating characteristic curves. These data suggested that miR-106a is a potential biomarker in the diagnosis of colorectal carcinoma. However, the underlying

molecular mechanism of miR-106a-promoted viability and inhibition of apoptosis requires further investigation.

## Introduction

Colorectal cancer (CRC) is one of the three most common types of cancer worldwide and is a major contributor to cancer-associated mortality (1). Effective screening to detect cancer is expected to decrease the mortality rate of CRC (2). Novel methods are currently under development for the detection of CRC, including those based on the detection of microRNAs (miRNA/miR) (3,4).

miRNAs are small (between 19 and 22 nucleotides) non-coding RNA molecules that are encoded by eukaryotic genomic DNA. miRNAs lead to translation repression or degradation of specific target mRNAs by directly binding to their potential target site in the 3' untranslated region (5). Located in the spacer regions between protein-coding genes or in the introns of protein-encoding genes, miRNA coding sequences are transcribed as primary miRNAs in the same manner as the mRNAs of the protein-coding genes (6). miRNAs are important mediators of biological functions, and their dysregulation has been implicated in a wide range of diseases, including malignancies, heart diseases, inflammation and lung diseases (7-9).

As identified previously, miR-28 suppresses viability, but activates metastasis in CRC cells (10), miR-381 increases radiosensitivity in esophageal squamous cell carcinoma (11), and miRNA-27b targets vascular endothelial growth factor C to inhibit tumor progression and angiogenesis in CRC (12).

miR-106a (miRBase accession number MIMAT0000103), located in Xq26.2, exhibits oncogenic activity in humans, and its expression is often altered in carcinogenesis (13). It has been demonstrated to be highly expressed in cancer tissues, including gastric carcinoma and ovarian cancer, and may be a potential biomarker in the diagnosis of certain malignant tumors (14-16).

In the present study, the expression levels of miR-106a were determined in CRC tissues and plasma, compared with the control group, and the potential association between the expression of miR-106a and clinicopathological factors of all patients was analyzed. In order to investigate the underlying molecular mechanism for the effects of miR-106, apoptosis of

CRC cells transfected with miR-106a mimic and miR-106a inhibitor was examined using flow cytometry.

## Patients and methods

**Patients.** In total, 42 patients with CRC (23 male, 19 female; median age, 63 years) and 42 healthy individuals (24 male, 18 female; median age, 60 years) were recruited from The First Hospital of Hebei Medical University (Shijiazhuang, China) between October 2013 and March 2014. No previous local or systemic treatment had been administered to the 42 patients with CRC prior to surgery. Written informed consent was obtained from all of the patients, in accordance with the protocols of the Ethics Review Board at Hebei Medical University (Shijiazhuang, China), which approved the present study.

**Samples.** A total of 42 pairs of CRC and non-tumor adjacent tissues were obtained from patients that underwent radical resection between October 2013 and March 2014 at The First Hospital of Hebei Medical University. The corresponding normal tissues were obtained from a section of the resected specimen  $\geq 5$  cm from the edge of the tumor. The samples were stored in liquid nitrogen or an  $-80^{\circ}\text{C}$  freezer until use.

Plasma samples were collected from 42 CRC patients prior to surgical resection and 7 days following surgery respectively. Furthermore, 42 plasma samples were obtained from 42 cases of age-matched healthy individuals as the control. Cell-free plasma was extracted from all blood samples within 2 h of collection using a two-step protocol at  $2,140 \times g$  for 10 min and  $12,840 \times g$  for 2 min. Plasma was transferred to fresh tubes and stored in a  $-80^{\circ}\text{C}$  freezer until use.

**Cell culture.** The human CRC cell line HCT116 was obtained from Professor Xiaofeng Sun (Division of Oncology, Department of Clinical and Experimental Medicine, Faculty of Health Sciences, Linköping University, Linköping, Sweden). Cells were cultured in McCoy's 5A medium (Gibco; Thermo Fisher Scientific, Inc., Waltham, MA, USA) containing 10% fetal bovine serum (Gibco; Thermo Fisher Scientific, Inc.) and 1% penicillin-streptomycin (Invitrogen; Thermo Fisher Scientific, Inc.) in a  $37^{\circ}\text{C}$  humidified incubator containing 5%  $\text{CO}_2$ .

**Quantitative miRNA analysis.** Total RNA was extracted from the frozen tissues using TRIzol reagent (Invitrogen; Thermo Fisher Scientific, Inc.), according to the manufacturer's protocol, and resuspended in  $60 \mu\text{l}$  pre-heated ( $95^{\circ}\text{C}$ ) nuclease-free water.

Total RNA was extracted from  $400 \mu\text{l}$  plasma samples using the miRNeasy Serum/Plasma kit (Qiagen GmbH, Hilden, Germany), according to the manufacturer's protocol, and eluted with  $105 \mu\text{l}$  pre-heated ( $95^{\circ}\text{C}$ ) double distilled water.

The concentration and purity of all RNA samples were detected using a NanoDrop ND-2000 spectrophotometer (NanoDrop Technologies; Thermo Fisher Scientific, Inc.). All RNA was stored at  $-80^{\circ}\text{C}$  until use following determination of the concentration RNA using a spectrophotometer.

Reverse transcription was carried out using the One Step PrimeScript<sup>®</sup> miRNA cDNA Synthesis kit (Takara Bio, Inc., Otsu, Japan), according to the manufacturer's protocol.

Quantitative polymerase chain reaction (qPCR) was performed using an All-in-One<sup>™</sup> miRNA qPCR kit (QP101; GeneCopoeia, Inc., Guangzhou, China) with an ABI 7500 Real-Time PCR system (Applied Biosystems; Thermo Fisher Scientific, Inc.), according to the manufacturer's protocol. All-in-One<sup>™</sup> miRNA qPCR Primers were used, including a hsa-miR-106a-5p primer pair (HmiRQP0026) and a HsnRNA U6 primer pair (HmiRQP9001; GeneCopoeia, Inc.). The PCR reaction mixture included  $10 \mu\text{l}$  2X All-in-One<sup>™</sup> qPCR mix,  $2 \mu\text{l}$  All-in-One<sup>™</sup> miRNA qPCR Primer,  $2 \mu\text{l}$  Universal Adaptor PCR Primer,  $2 \mu\text{l}$  template cDNA and  $4 \mu\text{l}$  double distilled water, for a total volume of  $20 \mu\text{l}$ . The reaction mixture was incubated at  $95^{\circ}\text{C}$  for 10 min, followed by 40 cycles of  $95^{\circ}\text{C}$  for 15 sec and  $60^{\circ}\text{C}$  for 60 sec. All RT-qPCR reactions were performed in triplicate.

U6 small nuclear RNA was used as a housekeeping gene to normalize miRNA expression, and the relative expression of miR-106a in CRC cells was determined using the comparative threshold cycle (Cq) method ( $2^{-\Delta\Delta\text{Cq}}$ ) (17).

**Cell Counting kit-8 (CCK-8) assays.** HCT116 cells were seeded into 96-well plates and then transfected with miR-106a mimic (miR10000103-1-5), miR-106a mimic control (miR01101-1-5), miR-106a inhibitor (miR20000103-1-5) or miR-106a inhibitor control (miR02101-1-5; all RiboBio, Guangzhou, China) using Lipofectamine 2000 (Invitrogen; Thermo Fisher Scientific, Inc.). At 24 h after culture, the cells were harvested and absorbance values at 450 were determined using CCK-8 reagent (Dojindo Molecular Technologies, Inc., Kumamoto, Japan) according to the manufacturer's protocol. Tests were performed in triplicate.

**Apoptosis assay.** Fluorescein isothiocyanate (FITC)-conjugated Annexin V and propidium iodide (PI) staining were performed by means of the Annexin V-FITC Apoptosis Detection kit (Neobioscience, Shenzhen, China). Following transfection with miR-106a mimic or inhibitor, or negative control, cells were cultured for 48 h, resuspended in 1X binding buffer, washed twice with PBS, and treated with Annexin V-FITC and PI. Following 10 min of incubation at room temperature in the dark, cells were submitted to flow cytometry with a BD FACS-Calibur flow cytometer calibrated with CaliBRITE beads, and the results were analyzed using CellQuest software (all BD Biosciences, San Jose, CA, USA). Tests were performed in quadruplicate.

Early apoptotic cells were located in the lower-right quadrant, late apoptotic or necrotic cells were located in the upper-right quadrant, normal cells were located in the lower-left quadrant and mechanically damaged cells were located in the upper-left quadrant of the flow cytometric dot plots (18).

**Statistical analysis.** Each experiment was conducted at least three times. All values are presented as the median and 25th and 75th percentiles or the mean  $\pm$  standard deviation. Differences were tested for significance using a Student's t-test, unpaired t-test, Mann-Whitney U test or a two-way analysis of variance followed by Tukey's post hoc test in SPSS software (version 19.0; IBM SPSS, Armonk, NY, USA).  $P < 0.05$  was considered to indicate a statistically significant difference.

(B) Relative expression of miR-106a in HCT116 cells transfected with miR-106a mimic or mimic control. (C) Cell viability of HCT116 cells transfected with miR-106a inhibitor or inhibitor control. (D) Relative expression of miR-106a in HCT116 cells transfected with miR-106a inhibitor or inhibitor control. P-values are expressed in comparison with the respective controls (Student's t-test). miR-106a, microRNA-106a; OD, optical density.

**Results**

*Effects of miR-106a on CRC cell viability.* Our previous study (19) identified that miR-106a expression was increased in the plasma of patients with CRC compared with healthy controls. Therefore, it was hypothesized that miR-106a expression may be associated with the progress of CRC. In the present study, the effects of miR-106a on cell viability and apoptosis in CRC cells were analyzed. First, to measure the effect of miR-106a on cell viability, a CCK-8 assay was carried out. HCT116 cells were transfected with miR-106a mimic or mimic control, miR-106a inhibitor or inhibitor control. Cell viability curves and, at 24 h after transfection, miR-106a expression were examined (Fig. 1).

The expression of miR-106a and cell viability were significantly upregulated by the miR-106a mimic comparison with mimic control in HCT116 cells ( $P < 0.01$ ; Fig. 1A and B, respectively). Conversely, following transfection with miR-106a inhibitor, the viability of HCT116 cells was also significantly decreased compared with inhibitor control-transfected cells ( $P = 0.0036$ ; Fig. 1C) and the expression of miR-106a was significantly decreased ( $P = 0.0004$ ; Fig. 1D). These results indicated that the miR-106a expression level was positively associated with CRC cell viability.

*Effects of miR-106a on CRC cell apoptosis.* The function of miR-106a on cell apoptosis was determined using flow cytometry. HCT116 cells were transfected with miR-106a mimic or mimic control, miR-106a inhibitor or inhibitor control. At 48 h after transfection, the apoptosis rates of HCT116 cells were determined (Fig. 2).

Following transfection with miR-106a mimic or mimic control, cell status was determined using flow cytometry, with early apoptotic cells located in the lower right quadrant of the plot (Fig. 2A and B). HCT116 cells transfected with miR-106a mimic exhibited a lower rate of early apoptosis compared with the control group. The mean  $\pm$  standard deviation early apoptosis rates were significantly decreased for the miR-106a mimic compared with the mimic control ( $8.68 \pm 0.75$  vs.  $12.45 \pm 1.16\%$ , respectively;  $P = 0.0016$ ;  $n = 4$ ; Fig. 2C).

Flow cytometry was also employed to analyze cells subsequent to transfection with an miR-106a inhibitor or an inhibitor control (Fig. 2D and E). HCT116 cells transfected with miR-106a inhibitor exhibited a higher rate of early apoptosis compared with the control group. The mean  $\pm$  standard deviation early apoptosis rates were significantly increased for the miR-106a inhibitor compared with the inhibitor control ( $8.803 \pm 0.27$  vs.  $6.733 \pm 0.60\%$ , respectively;  $P = 0.0162$ ;  $n = 4$ ; Fig. 2F).

These results indicated that the miR-106a mimic decreased early apoptosis in HCT116 cells, and that the miR-106a inhibitor increased early apoptosis in HCT116 cells, suggesting that miR-106a promoted cell viability by inhibiting early apoptosis in CRC cells.

*Expression of miR-106a is upregulated in human CRC tissues and plasma.* In previous studies (19), miR-106a expression was upregulated in the serum of patients with CRC. In the present study, the expression of miR-106a in human CRC tissues and plasma was determined. It was identified that the expression level of miR-106a was significantly upregulated in tumor tissues compared with adjacent tissues

Table I. Association between miR-106a expression in cancer tissues and clinicopathological characteristics of patients with colorectal cancer.

Variables	Patients (n=42)	miR-106a expression, median (25th and 75th percentile)	P-value

Poor	8	12.539 (5.423, 33.613)	
Moderate-well	34	35.731 (20.439, 60.149)	

<sup>a</sup>P<0.05, Mann-Whitney U test. miR-106a, microRNA-106a.

[median (25th percentile, 75th percentile, 26.2882 (14.5358, 49.3492) vs. 8.7187 (5.4891, 13.6726); P<0.0001; Fig. 3A]. The association between miR-106a expression in cancer tissues and clinicopathological characteristics of patients with CRC was also analyzed (Table I).

miR-106a expression in plasma of patients with CRC or healthy controls, and pre- or post-surgery in patients with CRC, was also investigated. The expression level of miR-106a in plasma was significantly higher in patients with CRC compared with in the healthy control group, consistent with our previous study (19) (P=0.0041; Fig. 3B). The healthy control group contained 42 age-matched healthy individuals with patients with CRC (data not shown). miR-106a expression in plasma post-surgery was decreased compared with in plasma pre-surgery, but no statistically significant difference was identified (0.16±0.18 vs. 8.80±40.50; P=0.1600; Fig. 3C). No significant association was identified between miR-106a expression in plasma and the clinicopathological parameters of the patients with CRC (data not shown). The sensitivity

and specificity of miR-106a were analyzed using a receiver operating characteristic curve in CRC diagnosis (Fig. 3D).

*miR-106a expression in CRC tissues is associated with differentiation and pathological type.* The expression of miR-106a in CRC tissues was identified to be associated with the differentiation and pathological type of tumor, by analyzing the clinicopathological characteristics of CRC patients. The expression level of miR-106a in CRC tissues was significantly increased in patients with adenocarcinoma compared with in patients with mucinous carcinoma (100.96±262.20 vs. 18.14±18.22; P=0.0348; Fig. 4A). miR-106a expression in CRC tissues was also increased in patients exhibiting moderate-well differentiation compared with that in patients exhibiting poor differentiation (108.87±272.79 vs. 18.12±19.20; P=0.0343; Fig. 4B).

The underlying molecular mechanism of increased miR-106a expression in adenocarcinoma and moderate-well differentiation CRC requires further investigation. No significant association

Figure 2. Effects of miR-106a on apoptosis of colorectal cancer cells. HCT116 cells were transfected with (A) mimic control or (B) miR-106a mimic, and (C) the proportion of cells in early apoptosis was quantified. HCT116 cells were transfected with (D) inhibitor control or (E) miR-106a inhibitor mimic, and (F) the proportion of cells in early apoptosis was quantified. Results are representative of at least 3 independent experiments. P-values were calculated with an unpaired t-test and are expressed in comparison with the respective controls. miR-106a, microRNA-106a; FITC, fluorescein isothiocyanate.

was identified between miR-106a expression and other clinicopathological characteristics, such as sex, age, distant metastasis, Dukes staging, tumor location and lymph node metastasis.

**Discussion**

miR-106a was identified to serve an oncogenic role in carcinogenesis (20,21). miR-106a enhanced the invasiveness of

human glioma stem cells, pancreatic cancer, gastric cancer and glioblastoma (22-24).

The results of the present study indicated that overexpression of miR-106a by transfection with miR-106a mimic increased the viability and suppressed early apoptosis of HCT116 cells. Knocking down the miR-106a expression by miR-106a inhibitor identified that cell viability was inhibited and the number of pro-apoptotic cells was upregulated. These

Figure 3. Expression of miR-106a is upregulated in human CRC tissues and plasma. miR-106a expression was determined in (A) CRC tissues and adjacent tissues, (B) plasma of patients with CRC and healthy controls, and (C) plasma of pre-surgery patients and post-surgery patients. (D) Receiver operating characteristic curve for the miR-106a discriminating patients with CRC from healthy controls. P-values are expressed in comparison with the respective controls (Mann-Whitney U test). miR-106a, microRNA-106a; CRC, colorectal cancer; op, operation; AUC, area under the curve.

Figure 4. Expression of miR-106a is associated with differentiation and pathological type in CRC tissues. (A) miR-106a expression in colorectal adenocarcinoma and colorectal mucinous carcinoma tissues. (B) miR-106a expression in poorly differentiated CRC tissues and moderately-well differentiated CRC tissues. P-values are expressed in comparison with the respective controls (Student's t-test).

results suggested that miR-106a served an important role in the viability and apoptosis of CRC cells.

miR-106a expression was determined in CRC tissues, and the association between miR-106a expression and clinicopathological data was analyzed. The expression level of miR-106a in CRC tissues was significantly upregulated in CRC tissues compared with adjacent tissues. More importantly, an increased association was identified between miR-106a expression and pathological type, differentiation and depth of invasion. The expression levels of miR-106a were increased in adenocarcinoma compared with mucinous carcinoma ( $P=0.0423$ ). The expression of miR-106a was identified to be positively

associated with differentiation. The well-differentiated CRC tissues exhibited an increased expression level of miR-106a compared with poorly differentiated CRC tissues ( $P=0.0382$ ). However, miR-106a expression was not identified to be associated with other clinicopathological characteristics, including sex, age, distant metastasis, Dukes staging, tumor location and lymph node metastasis ( $P>0.05$ ). These results are in contrast with a previous study identifying that miR-106a exhibited an increased expression level in rectal tumors (25).

A number of studies have focused on circulating miRNAs, which have been reported as an effective and non-invasive biomarker for detecting various cancers or other diseases (26-28).

In our previous study, the plasma level of miR-106a was significantly increased in patients with CRC compared with healthy controls (19). The expression of miR-106a was also determined in the plasma of 40 patients with CRC and 40 healthy individuals, and the expression level of miR-106a was significantly increased in patients with CRC compared with in the healthy control group. In the present study, although the plasma levels of miR-106a were analyzed in patients with CRC at different clinical status (age, tumor size, tumor-node-metastasis stage or metastasis), no significant difference was identified. No significant alterations in the miR-106a expression were identified following surgery compared with its preoperative level, which is in contrast with previous results (19). It is hypothesized that this may be due to the limited sample size. Therefore, expanding the sample size in future research may provide more insight into the underlying molecular mechanism.

It was hypothesized that miR-106a served an important role in carcinogenesis of CRC. In the present study, the focus was on analyzing the effect of miR-106a in CRC cell apoptosis, viability and the alterations in miR-106a expression in CRC tissues.

miR-106a may be a potential biomarker in the diagnosis of CRC, particularly in the diagnosis of colorectal adenocarcinoma. miR-106a serves important roles in the differentiation of colorectal adenocarcinoma, CRC progression, CRC cell viability and apoptosis. miR-106a may be associated with the migration and invasion of cancer cells. Increased accuracy could be obtained if a number of types of circulating miRNAs are combined to provide a clinical diagnosis of CRC. Further research is required to elucidate the role of miR-106a in tumor progression and its complicated interactions with oncogenes and tumor suppressors. Further study is required to elucidate the underlying molecular mechanism of miR-106a in the development of CRC.
