Abstract. Anaplastic thyroid cancer (ATC) constitutes one of the most aggressive types of human solid cancer, and is characterized by the absence of thyroid differentiation features and a marked degree of invasiveness. We have previously demonstrated that the RNA-binding protein Hu antigen R (HuR) is overexpressed in thyroid carcinoma; thus, the biological role of this RNA-binding protein was investigated in the present study using the ATC cell lines SW1736 and 8505C. In both cell lines, HuR protein levels were higher compared with in the non-tumorigenic thyroid cell line Nthy-ori-3.1. HuR silencing by RNA interference in both ATC cell lines decreased cell viability, increased apoptosis rates and reduced the capability to form colonies in soft agar. Thus, HuR plays an important role in the proliferation and aggressiveness of ATC cells. The histone deacetylase inhibitor suberoylanilide hydroxamic acid (SAHA) was able to reduce the viability of ATC cells. The results demonstrated that SAHA was able to decrease HuR expression in SW1736 and 8505C cells. Furthermore, since it is known that the transcription factor nuclear factor (NF)- κ B modulates HuR expression, whether SAHA affects the nuclear (active) fraction of NF- κ B in ATC cells was investigated. The data suggested that SAHA decreases ATC cell viability by reducing the active form of NF- κ B, which, in turn, modulates HuR expression.

Introduction

In the last years, it was attested that the most important eukaryotic mechanisms of gene expression regulation occurs at post-transcriptional level (1). These mechanisms are altered in several diseases, including cancer, and this could be due to an aberrant expression and activity of RNA-binding proteins (RBPs) (2,3). These proteins are key regulators of

post-transcriptional gene expression and among them, one the most known RBP to be implicated in tumorigenesis is Hu antigen R (HuR) (4-6).

HuR is the ubiquitously expressed member of the Hu family and it is involved in regulation of mRNA stability and translation. HuR is located into the nucleus and, in response to stimuli, can shuttle to the cytoplasm to allow its mRNA target to be processed. Several studies demonstrated that HuR is overexpressed and delocalized in the cytoplasm in numerous cancers, including breast cancer, lung adenocarcinoma, ovarian cancer, laryngeal squamous cell cancer and colon cancer (6,7). Moreover, various mRNA of tumorigenesis factors, oncogenes and anti-apoptotic factors have been identified as HuR targets (5). In a previous study, we demonstrated that HuR is overexpressed also in thyroid cancer (8).

Thyroid cancer is the most widespread endocrine malignancy and although it represent only the 1-2% of all human neoplasms, its incidence is rapidly growing all over the world in the last decades (9). In most cases, thyroid carcinomas derived from follicular cells and could be classified as differentiated carcinomas, that include follicular thyroid cancer (FTC) and papillary thyroid cancer (PTC), and undifferentiated carcinomas, also named anaplastic thyroid cancer (ATC) (10).

ATC constitute one of the most aggressive and lethal human solid tumor and is characterized by an absence of thyroid differentiation features, a marked degree of invasiveness and extensive necrosis (11). ATC patients have a median survival of 5 months and less than 20% survive 12 month. Nowadays there are not effective therapies for ATC, since surgery, traditional chemotherapies and radiation therapies are mostly ineffective and are not able to improve the overall survival (10,11). Therefore, innovative approaches for ATC treatment are needed.

Materials and methods

Cell lines. Nthy-ori-3.1, derived from normal thyroid follicular epithelial cells and immortalized by the SV40 large T gene, SW1736 and 8505C cell lines, from ATC, were grown in RPMI1640 medium (Euro Clone, Milan, Italy) supplemented with 10% fetal bovine serum (Gibco Invitrogen, Milan, Italy), 2 mM L-glutamine (Euro Clone) and 50 mg/ml gentamicin (Gibco Invitrogen). Cultured cells were treated with either vehicle (DMSO; Sigma-Aldrich; Merck KGaA, Darmstadt, Germany) or suberoylanilide hydroxamic acid (SAHA)

Key words: HuR, RNA-binding proteins, anaplastic thyroid cancer, SAHA, siRNA

(Cayman Chemical, Ann Arbor, MI, USA). Cells were grown in a humidified incubator (5% CO₂ in air at 37°C) (Eppendorf AG, Hamburg, Germany). All cell lines have been validated by short tandem repeat and tested for being mycoplasma-free.

Protein extraction and western blot. Total protein extraction was performed harvesting Nthy-ori-3.1, SW1736, and 8505C cells by scraping and lysing cells with total lysis buffer (Tris HCl 50 mM pH8, NaCl 120 mM, EDTA 5 mM, Triton 1%, NP40 1%, DTT 1 mM), supplemented with phenyl-methylsulphonyl fluoride and protease inhibitors. Lysates, then, were centrifuged at 13,000 x g for 10 min at 4°C and supernatants were quantified by Bradford assay.

For western blot analysis, proteins were electrophoresed either on 7.5, 10 or 12% SDS-PAGE and then transferred to nitrocellulose membranes (GE Healthcare, Little Chalfont, UK), saturated with 5% non-fat dry milk in PBS/0.1% Tween-20. The membranes were then incubated overnight with rabbit polyclonal anti-HuR antibody 1:500 (EMD Millipore, Billerica, MA, USA), rabbit anti-PARP antibody 1:400 (Abcam, Cambridge, UK), rabbit anti-nuclear factor (NF)-κB antibody 1: 200 (Santa Cruz Biotechnology, Inc., Dallas, TX, USA), rabbit anti-actin antibody 1:1,000 (Abcam) or rabbit anti-LSD1 antibody 1:1,000 (Abcam). The day after, membranes were incubated with anti-rabbit immunoglobulin coupled to peroxidase 1:4,000 (Sigma-Aldrich) for 2 h. Blots were developed using UVITEC Alliance LD (UVItec Ltd., Cambridge, UK) with the SuperSignal Technology (Thermo Fisher Scientific, Inc., Waltham, MA, USA).

HuR silencing. For transient silencing of endogenous HuR in SW1736 and 8505c cells, TriFECTa RNAi kit (Integrated DNA Technologies Inc., Coralville, IA, USA) was used following manufacturer's instructions. A duplex targeting a site absent in human genome was used as 'universal' negative control. Three different siRNA oligonucleotides (siRNA1, siRNA2 and siRNA3) were transfected at a concentration of 1 nM using DharmaFECT 1 Transfection reagent (Thermo Fisher Scientific, Inc.), according to manufacturer's instructions. The day before transfection, cells were plated in antibiotics-free medium. Cells were harvested 72 h after transfection and gene-silencing efficiency was evaluated by protein levels analysis.

Cell viability. In order to test cell viability, we applied the methyl thiazolyl tetrazolium assay (MTT) assay. SW1736 and 8505C cells (3,000 cells/well) were plated onto 96-well plates in 200 μl medium/well and were allowed to attach to the plate for 24 h (t0). Plates were then incubated for 24, 48 and 72 h. 4 mg/ml MTT (Sigma-Aldrich) was then added to the cell medium and cells were cultivated for another 4 h darkened in the incubator. The supernatant was removed, 100 μl/well of DMSO (Sigma-Aldrich) were added and the absorbance at 570 nm was measured. All experiments were run in quadruplicate and cell viability was expressed as a fold-change compared to control.

Soft agar assay. SW1736 and 8505C cells clonogenic activity after HuR silencing was evaluated by soft agar assay.

Briefly, after 72 h HuR silencing, cells have been collected and 10,000 cells/plate were suspended in 4 ml of complete medium containing 0.25% agarose and then seeded to the top of a 1% agarose complete medium layer in 6 cm plates. The colonies were counted on an inverted microscope Leica DMI-600B (Leica Microsystems Ltd., Heerbrugg, Switzerland). Data are representative of three independent experiments.

Gene expression assays. 500 ng of total RNA of SW1736 and 8505C cells, treated with SAHA or vehicle, were reverse transcribed to cDNA using random exaprimers and MMLV reverse transcriptase (Life Technologies; Thermo Fisher Scientific, Inc.). Real-time PCR was performed using Platinum SYBR-Green qPCR supermix (Life Technologies; Thermo Fisher Scientific, Inc.) on the ABI Prism 7300 Sequence Detection Systems (Applied Biosystems). The ΔΔCq method, by means of the SDS software (Applied Biosystems; Thermo Fisher Scientific, Inc.), was used to calculate mRNA levels. Oligonucleotide primers were purchased from Sigma-Aldrich and their sequences are available upon request.

Statistical analysis. All data obtained are expressed as means ± standard deviation, and significances were analyzed with the Student's t-test performed with GraphPAD Software for Science (San Diego, CA, USA).

Results

Since we had previously demonstrated the *in vivo* HuR overexpression in thyroid cancer and considering the necessity to identify innovative approaches for ATC treatment, in this study we focused on the expression and the importance of HuR in ATC cells. To this purpose, we evaluated HuR protein levels in a normal (Nthy-ori-3.1) and in two ATC (SW1736 and 8505C) cell lines. The Western Blot analysis displayed a significant HuR overexpression in both ATC cells (Fig. 1), confirming data obtained *in vivo* (8).

In order to evaluate the importance of HuR and its biological effects in ATC cells, we performed an RNA interference assay. In a first set of experiments, we performed the silencing using three different HuR-specific siRNA (1 nM). As shown in Fig. 2A and B, in both SW1736 and 8505C cell lines, siRNA 1 and 2 induces a strong HuR silencing, while siRNA 3 seems to have no effects on the RBP expression. Then, we investigated HuR silencing effects on cell viability, apoptosis and clonogenic ability. In both cell lines, 1 nM siRNA 1 treatments induce a slight (about 20%), but significative cell viability reduction (Fig. 2C). In order to measure HuR silencing effects on apoptosis, we performed a Western Blot analysis of PARP, a well-known caspase substrate that is specifically cleaved during apoptosis (12). As shown in Fig. 2D, siRNA 1 increases apoptosis phenomena compared to control, in both SW1736 and 8505C cells. Since mRNA of genes involved in cell aggressiveness have been identified among known HuR-targets, we investigated the ability of SW1736 and 8505C to form colonies in soft agar, after HuR-silencing. We detected a 40% reduction of clonogenic ability after siRNA 1 treatments in both SW1736 and 8505c cells (Fig. 2E). Therefore, all these data indicate that HuR

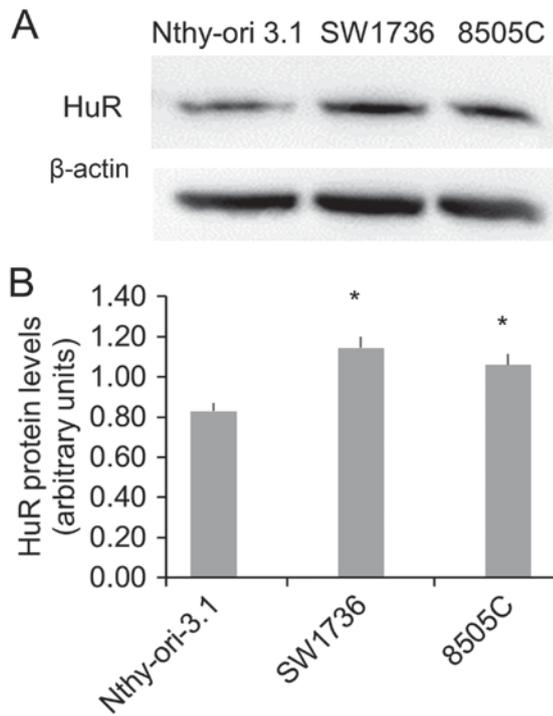

Figure 1. HuR expression in ATC cell lines. (A) Western blot analysis of HuR expression in a non-tumorigenic thyroid cell lines (Nthy-ori-3.1) and in two ATC-derived cell lines (SW1736 and 8505C). (B) Densitometric analysis of HuR protein levels in thyroid cell lines. For each cell line, the results were normalized against β -actin levels and expressed in arbitrary unit. plays a positive role in cell proliferation and in colonies forming ability in ATC-derived cell lines.

Histone deacetylase (HDAC) inhibitors are an important class of anticancer agents. One of the most known HDAC inhibitor is the SAHA, that is able to induce cell growth arrest and apoptosis in different cancer cell lines (13). In a previously study, we have demonstrated how SAHA $3 \mu\text{M}$ treatment lead to decrement of cell viability in the SW1736 cell line (14). Besides, Zhang *et al* have demonstrated that the treatment with SAHA induces a reduction of HuR protein expression in mouse epidermal JB6 Cl41 cells (15).

For this reason, after confirming SAHA-related reduction cell viability in 8505C cells (data not shown), we focused on SAHA effects on HuR protein levels in the two ATC cell lines, in order to determine if SAHA effects in ATC is also due to HuR downregulation. We evaluated, at different time point, whether a $3 \mu\text{M}$ SAHA treatment significantly altered HuR mRNA and protein levels in SW1736 and 8505C cells (Fig. 3). After 48 h SAHA treatment, a reduction about 60 and 50% of HuR mRNA levels has been detected in SW1736 and 8505C, respectively (Fig. 3A). Thereafter, HuR protein levels have been evaluated after 72 h SAHA $3 \mu\text{M}$ treatment. As shown in Fig. 3B and C, SAHA induces a strong HuR protein levels decrease in both cell lines.

To define whether SAHA treatment operate directly on HuR transcription or involve other factors implicated in its regulation, we evaluated NF- κB protein levels. Kang *et al* have demonstrated that NF- κB , binding HuR promoter, directly activates its transcription to promote tumorigenesis (16). NF- κB is a transcription factor implicated in various aspects of tumor

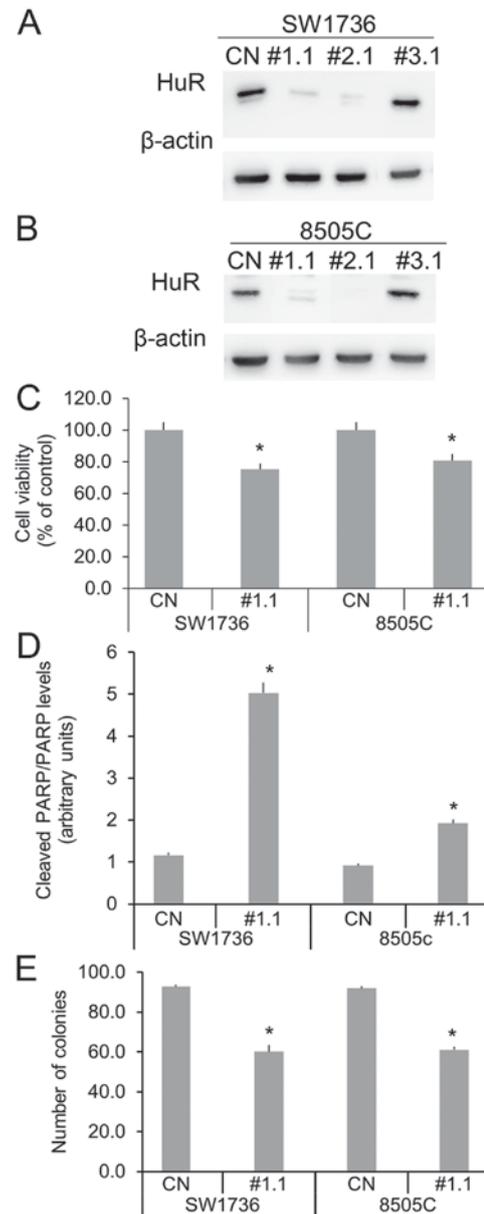

Figure 2. Biological effects of HuR silencing in ATC cells. (A) SW1736 and (B) 8505C cells were transfected with non-targeting siRNA (CN, negative control) or three different siRNA (1, 2 and 3) sequence specific to HuR (1 nM) and collected after 72 h treatment. HuR protein levels were analyzed by western blot analysis, as described in Materials and methods section. For each cell line, the results were normalized against β -actin levels and expressed in arbitrary unit. (C) SW1736 and 8505C cells were transfected to either siRNA1 (#1.1) or CN for 72 h and cell viability was analyzed by MTT assay. (D) Densitometric analysis of cleaved PARP fraction levels obtained with western blot assay in SW1736 and 8505C cells transfected to either siRNA1 (#1.1) or CN for 72 h. (E) Histogram representing the number of colonies per cell line evaluated by colony formation assay of SW1736 and 8505C transfected to either siRNA1 (#1.1) or CN for 72 h. biology, such as cell proliferation, survival, angiogenesis, invasion, metastasis and drug resistance. Inactivated NF- κB localized in the cytoplasm and complexed with the inhibitory protein I $\kappa\text{B}\alpha$ while activated NF- κB is translocated into the nucleus where it binds its DNA target sequences (17,18).

In order to evaluate activated NF- κB levels, we performed a Western Blot analysis on ATC cells nuclear fraction, treated or not with SAHA. Data obtained show that SAHA

administration induces a significant reduction of nuclear NF- κ B fraction after 24 and 48 h in both SW1736 and 8505C cells (Fig. 4). These results demonstrate that SAHA treatment reduces activated NF- κ B levels in ATC cells.

Discussion

HuR is a RNA-binding protein that plays a major role in regulating gene expression (19) and that can contribute to tumorigenesis (4). *HuR* transcription is positively regulated

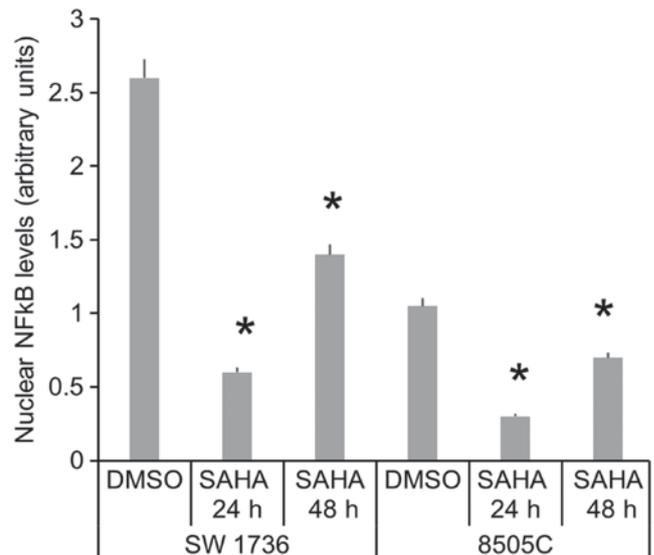

Figure 4. Effects of SAHA treatment on activated NF- κ B levels in ATC cell lines. Densitometric analysis of nuclear NF- κ B protein levels in SW1736 and 8505C cell lines after DMSO or SAHA 3 μ M administration for 24 or 48 h. For each cell line, the results were normalized against LSD1 expression and expressed in arbitrary unit. Results are shown as mean \pm standard deviation. * P <0.05 by Student's t-test.

by the NF- κ B or by Smad, while the levels of its mRNA and protein are conditioned upon multiple regulation mechanisms (16,19). Several studies indicate that HuR expression and localization are modified in different cancer types, including thyroid cancer (4,14). ATC, although is a rare thyroid cancer histotype, is characterized by a very poor prognosis and a complete absence of differentiation markers (20). Current treatments, based on combination of surgery, chemotherapy and external radiotherapy, are not effective. Therefore, new therapies for ATC are particularly needed.

In order to find new strategies to treat this aggressive thyroid cancer subtype, we investigated HuR expression and its biological effects in two ATC-derived cell lines, SW1736 and 8505C. Therefore, we have demonstrated that HuR is overexpressed in ATC cells and that its silencing determine cell viability reduction due to an increase in apoptosis processes, in both cell lines. Focusing on HuR involvement in cell tumorigenicity, we have established that HuR silencing reduces ATC cells colony forming ability. In this way, we have proved, for the first time, the importance of HuR in ATC cell lines in terms of cell viability, cell death and tumor aggressiveness. Therefore, HuR could be a possible therapeutic target for ATC treatment.

Consequently, in a second experimental setting, we focused on substances able to reduce HuR expression in thyroid cancer. In particular, SAHA, a HDAC inhibitor already FDA-approved for the treatment of several neoplastic diseases (21), proved to induce HuR downregulation in mouse epidermal JB6 C141 cells (15). Moreover, in a previous study, we demonstrated SAHA effects on SW1736 cell viability (14), and in this study, these data have been confirmed also in 8505C cells. Our data shown that SAHA induces a strong HuR mRNA and protein levels reduction, in both ATC cell lines. To better understand the mechanism through which SAHA induces

HuR downregulation, we investigate the effects of this drug on NF- κ B, which is the major transcription factor of *HuR* (16). In SW1736 and 8505C cell lines, SAHA treatment determines a decrease of activated NF- κ B protein levels. This data corroborate the idea that SAHA effects on HuR expression are not direct, but could be due to its effects of NF- κ B.

In conclusion, our findings indicate, for the first time, that the RBP HuR plays an important role in ATC tumorigenesis. Moreover, we have demonstrated that the HDAC inhibitor SAHA could be used to obtain a HuR downregulation as consequences of reduction of NF- κ B activation.
