Abstract. It is known that an epidermal growth factor receptor (EGFR) gene mutation(s) is present in a percentage of non-small cell lung cancers (NSCLCs). Gefitinib, an inhibitor of the tyrosine kinase activity of EGFR, is effective on most of them. The EGFR mutation status alone cannot fully predict the response to gefitinib and the prognosis for the patients. We hypothesized that information on the expression levels of phosphorylated-EGFR and -Akt, and E-cadherin, alone or in combination with information on the EGFR mutation, may refine our ability of prediction. We investigated 24 NSCLCs that had recurred after surgery and were treated with gefitinib. Specimens resected by surgery were subjected to the peptide nucleic acid-locked nucleic acid polymerase chain reaction clamp reaction to determine the EGFR mutation status, and to immunohistochemical staining of phosphorylated-EGFR and -Akt, and E-cadherin to determine their expression levels. The EGFR mutation status was predictive of responsive disease (complete response: CR + partial response: PR) and controlled disease (CR + PR + stable disease: SD). Positive E-cadherin staining was predictive of longer time to progression (12.4 vs. 5.9 months, $p < 0.05$) and overall survival (OS) (18.4 vs. 13.0 months, $p < 0.05$). Together the patients with an EGFR mutation and the patients with positive E-cadherin staining defined a patient group with a median OS of 18.4 months and excluded the patient group with the median OS of 3.7 months. Neither p-Akt nor p-EGFR staining was associated with the response and survival. In

patients with surgically resected NSCLC tumors, the EGFR mutation status and E-cadherin staining can select patients who will benefit from gefitinib therapy.

Introduction

Gefitinib (ZD1839, Iressa, AstraZeneca, Wilmington, DE) is a therapeutic reagent for non-small cell lung cancers (NSCLCs). It shows dramatic anti-tumor effects in some patients, but has no effect in others (1). The presence of an epidermal growth factor receptor (EGFR) gene mutation(s) (hereafter EGFR mutation) associates significantly with the gefitinib responsiveness (2,3) and serves as a marker in the choice of therapeutic regimens (4). Some tumors with an EGFR mutation do not respond to gefitinib therapy while those with wild-type gene do (5-7), so additional markers are required to more precisely select tumors that respond to gefitinib.

EGFR transmits signals that direct cell proliferation and survival. The wild-type EGFR preferentially transmits cell proliferation signals through Erk, while the mutant EGFR preferentially transmits cell survival signals through Akt or STAT (8). Gefitinib effectively inhibits the latter (2). This is why gefitinib selectively elicits an apoptotic response in cells with an EGFR mutation, thereby producing its clinical response (8). We hypothesized that molecules that interact with EGFR or are located downstream in the pathway modify the tumor cell response to gefitinib and therefore serve as markers that may help to more precisely predict their responsiveness to gefitinib.

In this study, three molecules were tested for their predictive ability, p-EGFR (phosphorylated at Tyr1173: pTyr1173), p-Akt (phosphorylated at Ser473: pSer473) and E-cadherin, in addition to the EGFR mutation status. p-EGFR(pTyr1173) transmits a signal that directs cell proliferation (9), p-Akt(pSer473) mediates signals that direct cell survival (10) and E-cadherin has been shown to interact with EGFR by modifying its activity (11). We investigated the expressions of these three molecules by immunohistochemistry

Key words: non-small cell lung cancer, gefitinib, E-cadherin, epidermal growth factor receptor mutation

in 24 NSCLCs that had been resected by surgery, recurred afterward and were treated with gefitinib. The results enabled us to test their staining intensity, alone, or in combination with the EGFR mutation status. It also improved our ability to predict the responsiveness to gefitinib and patient outcome.

Materials and methods

Patients. This study was approved by the Tsuboi Cancer Center Hospital ethics board. After the written informed consent was obtained, we enrolled 24 Japanese patients who had suffered from lung cancers which were resected between 1996 and 2004 (Tsuboi Cancer Center Hospital, Fukushima, Japan) and then had recurred. The patient characteristics are summarized in Table I. Gefitinib, 250 mg per day, was initiated between July 2002 and October 2006 to treat the recurrent disease. The median time between the surgery and the start of the gefitinib treatment was 740 days (range: 113-2,012). Treatment was continued until the disease progressed, intolerable toxicity developed or a patient refused treatment for other reasons.

Evaluation of the response to gefitinib and patient outcome. Every 4 weeks chest X-rays or computed tomography (CT) scans were done to evaluate tumor response and lung toxicity, and blood tests were done to monitor systemic toxicity. Tumor response that remained stable for at least 30 days was graded according to the Response Evaluation Criteria in Solid Tumors (12). Time to progression (TTP) in these patients was defined as the interval from the start of gefitinib administration to disease progression or death. The outcomes were evaluated up to May 31, 2007, with an average follow-up time of 20.6 months (range: 1.1-50.0). Both mutation and immunohistochemical analyses were performed after completion of the response evaluation.

DNA extraction and mutation analysis. DNA was extracted from the paraffin-embedded tumor tissue (13-15). EGFR mutations were detected using the peptide nucleic acid-locked nucleic acid (PNA-LNA) polymerase chain reaction (PCR) clamp. This method, which has been described in detail elsewhere, is a rapid and sensitive detection system for EGFR gene mutations and can detect point mutations G719C, G719S, L858R and L861Q and deletions in exon 19 in the presence of a 100- to 1,000-fold background of wild-type EGFR (4,6,16).

Immunohistochemistry and scoring. Formalin-fixed, paraffin-embedded tumor tissue was tested for immunoreactivity to p-EGFR, p-Akt and E-cadherin. The primary antibodies used were: anti-p-EGFR that detects EGFR protein phosphorylated at Tyr1173 (Cell Signaling Technology Beverly, MA), anti-p-Akt that detects Akt protein phosphorylated at Ser473 (Cell Signaling Technology) and anti-E-cadherin (BD Biosciences, Beverly, MA). Tissue sections cut at a thickness of 5 μ m were placed on glass slides, deparaffinized and then rehydrated. Antigen was quantified using the following procedure. The slides were incubated in citrate buffer in a steamer for 15 min. Endogenous peroxidase activity was quenched by incubating the slides in 3% hydrogen peroxide for 5 min and non-specific background staining was blocked by incubation in a protein

block for 5 min. Sections were then reacted with primary antibody dilutions (p-EGFR a 1/400 dilution at 37°C for 15 min, p-Akt a 1/50 dilution at 4°C for 16 h and E-cadherin a 1/100 dilution at 37°C for 32 min). The bound antibody was detected by biotinylated secondary antibody and visualized using diaminobenzidine (DAB) chromogen. Sections were then counterstained with Mayer's hematoxylin and mounted using the resinous mounting medium.

The p-EGFR and p-Akt stainings were scored by their cytoplasmic and nuclear staining, while E-cadherin staining was scored by its membrane staining (17-19), all without the knowledge of clinical or laboratory information. The cytoplasmic and nuclear staining of the entire tumor was scored as follows: First, 500 randomly selected tumor cells (50 cells per randomly chosen microscopic field at x40 magnification) were scored as 0 (no staining), 1 (mild), 2 (moderate) or 3 (strong staining). Second, for p-EGFR, the most intense staining observed in >1% of the cells was the staining score for the tumor. For p-Akt, the mode of the cytoplasmic or nuclear staining score, whichever was greater, was the staining score for the tumor. Tumors with staining scores of 0 or 1 were ranked negative and scores of 2 or 3 were ranked positive. The membrane staining of the entire tumor was scored as 0 when no tumor cells were stained, 1 when <10%

Table II. Response to gefitinib therapy.

	CR	PR	SD	PD	NE
No. of patients	0	8	6	5	5
Median TTP (months)		16.1	9.3	1.0	
Median OS (months)		25.9	20.8	6.5	

TTP, time to progression; OS, overall survival; CR, complete response; PR, partial response; SD, stable disease; PD, progressive disease; NE, not evaluated.

showed weak membrane staining, 2 (weakly positive) when >10% showed complete membrane staining although with weak to moderate intensity and 3 (strongly positive) when >10% had complete and strong membrane staining. Entire tumors with staining scores of 0 or 1 were considered negative while those scored as 2 or 3 were considered positive.

Statistical analyses. All statistical analyses were performed by StatView version 5 software (SAS institute Inc, Cary, NC). Comparisons of the proportions between two populations utilized the χ^2 test. Comparisons of patient outcome (TTP and overall survival, OS) between patient groups utilized the Kaplan-Meier method and the log-rank test. All statistical tests were two-sided and $P < 0.05$ was considered significant.

Results

Response to the gefitinib and patient outcome. The responses to gefitinib are summarized in Table II. The responders [complete response: CR + partial response: PR, (8/24) 33%] had significantly longer TTP and OS than non-responders ($p < 0.005$ and $p < 0.05$, respectively). In addition, the patients with controlled disease [CR + PR + stable disease: SD (13/24) 54%] had significantly longer TTP and OS ($p < 0.001$ and $p < 0.001$, respectively). We found no significant differences in the OS between patients with PR and SD nor could we prove that CR + PR better defined patients who benefited from the therapy than CR + PR + SD. We therefore performed the analyses based on the two groupings.

Analyses of the EGFR mutation status and staining of p-EGFR, p-Akt and E-cadherin. We investigated the EGFR mutation status and the staining of p-EGFR, p-Akt and E-cadherin. We chose these proteins because they are intimately connected with the activity of EGFR and thus may predict responsiveness to gefitinib and/or patient outcome. In the mutation analysis, 10 patients were found to have an EGFR mutation: one had a point mutation L858R(T2573G), two had a deletion E746-A750del(2235-2249del), six had a deletion E746-A750del(2236-2250del), and one had a deletion L747-S752del, P753S(2240-2257del). All these mutations have been observed in gefitinib responders in the literature (2,3). Representative immunohistochemical staining is shown in Fig. 1 with the

results summarized in Table III. The results of the EGFR mutation status are also shown. Positive p-Akt staining was associated with EGFR mutation, which is plausible because mutant EGFR stimulates the cell survival signal that is mediated by p-Akt. The staining intensity of p-EGFR and E-cadherin failed to show an association with the EGFR mutation and thus may be an independent parameter.

Predictors of the responsiveness to gefitinib. We then investigated the association between the expression of these proteins and the responsiveness to gefitinib (Table IV). The presence of an EGFR mutation significantly associates with responsive diseases (CR + PR) or controlled diseases (CR + PR + SD). This is consistent with the results presented in previous reports (20-22). We found no significant associations in the staining result for p-EGFR, p-Akt and E-cadherin.

Predictors of patient outcome. We compared the Kaplan-Meier curves to identify predictors of longer TTP and/or OS. As shown in Fig. 2A the positive staining of E-cadherin predicts a longer TTP (12.4 vs. 5.9 months, $p < 0.05$) and longer OS (18.4 vs. 13.0 months, $p < 0.05$). The presence of EGFR mutation(s) ($p = 0.13$ and $p = 0.11$, respectively, Fig. 2B), as well as p-EGFR and p-Akt staining intensity failed to predict outcome. We then looked at the EGFR mutation status in conjunction with the E-cadherin staining intensity as predictors of these same parameters. As shown in Fig. 2C in the right panel, the patients with EGFR mutation-positive tumors and those with E-cadherin-positive tumors defined a patient group with a median OS of 18.4 months and excluded the patient group with the median OS of 3.7 months, although we failed to show a significant difference in TTP (Fig. 2C, left panel). Therefore, we consider that the patients with EGFR mutation-positive or E-cadherin-positive tumors are the most likely to benefit from gefitinib therapy.

Discussion

It was shown that NSCLC tumors with an EGFR mutation(s) respond to gefitinib at a rate of 65 to 100% (5-7,20-24). Several prospective phase II studies have shown that gefitinib therapy significantly lengthened TTP in NSCLC patients with EGFR mutation-positive tumors (5-7). Thus far, no prospective studies have reported on OS. Several retrospective studies have suggested that gefitinib therapy may result in a longer OS in patients with EGFR mutation-positive tumors (20,21,23), however, we did not observe any significant differences in either TTP or OS. This is likely due to the size of the current study, as is discussed later.

We showed that positive E-cadherin staining is significantly associated with TTP and OS. Possible mechanisms that may explain this observation include that i) tumors with a lower E-cadherin expression progress faster than those with a higher expression and ii) E-cadherin modifies EGFR function and thus contributes to the effect of gefitinib treatment. The former mechanism is supported in reports that show that tumors with a positive E-cadherin staining are more frequent in early stage than in locally advanced or metastasizing NSCLCs (25-28). Similar results have been obtained in other malignancies such as the esophagus (29,30), stomach (31,32), colon (33),

liver (34), pancreas (35) and urinary bladder (36,37). Moreover, in NSCLCs, a positive E-cadherin expression associates with a more differentiated histology (26,28) and a better prognosis (25,27,28). The latter mechanism is supported by reports showing that E-cadherin interacts with EGFR,

thereby decreasing ligand-affinity (38,39) and inhibiting activation (40) in several human tumor types including the esophageal, breast and lung (41-43). Mechanisms i) and ii) stated above are not mutually exclusive and both may contribute to a better prognosis.

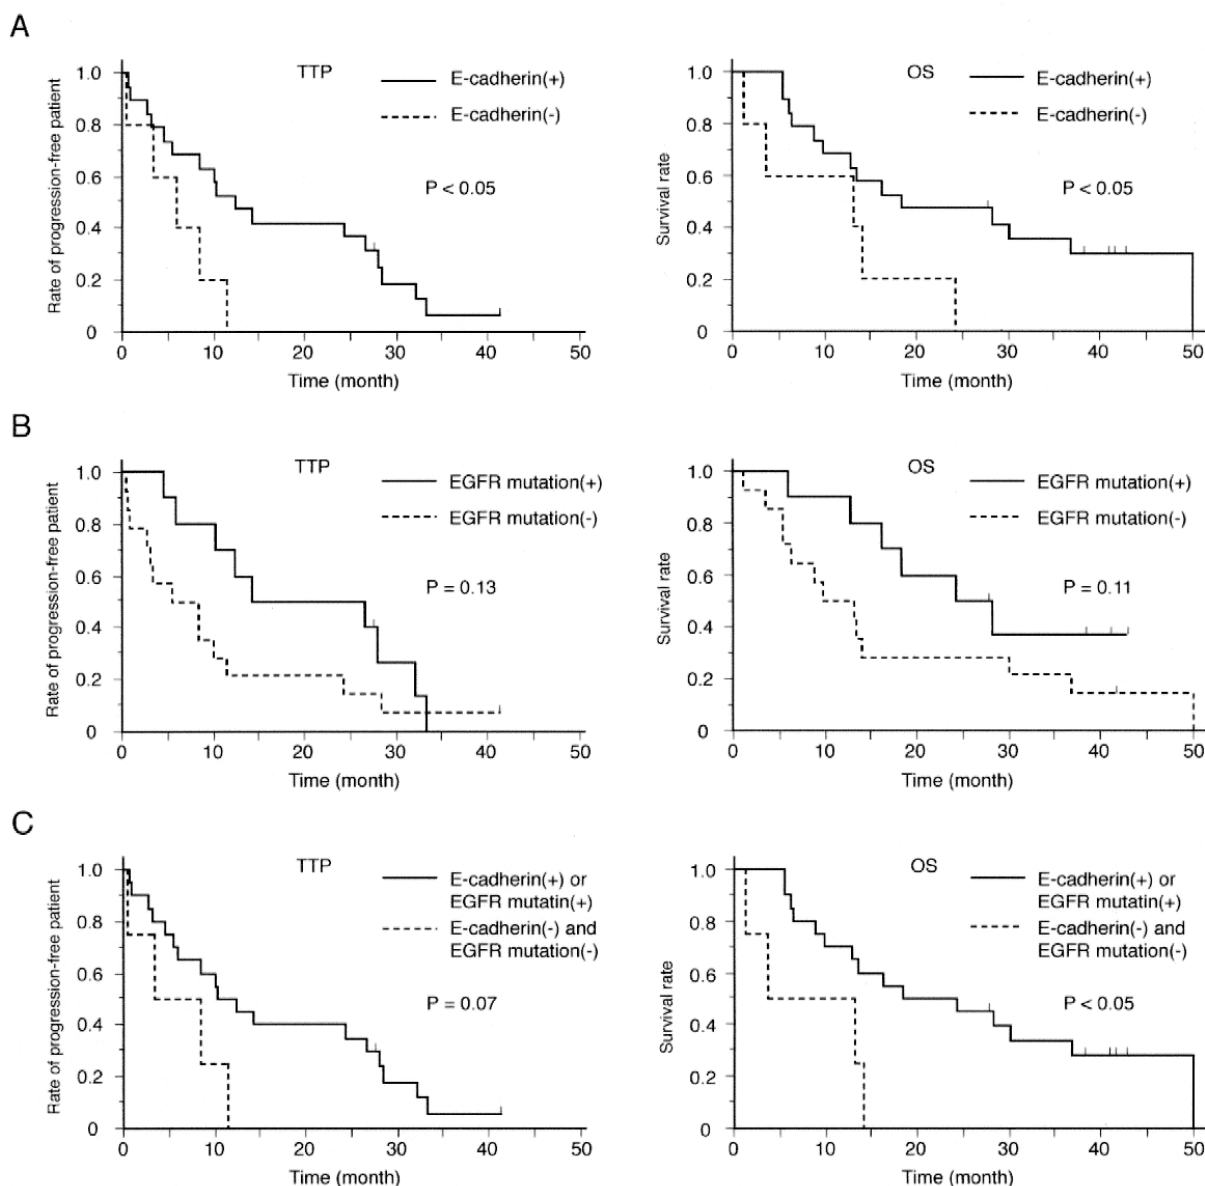

Figure 2. (A) Kaplan-Meier plots of TTP and OS where patients are grouped by the E-cadherin staining of their tumors. (B) Kaplan-Meier plots of TTP and OS where patients are grouped by the EGFR mutation status of their tumors. (C) Kaplan-Meier plots of TTP and OS where the two groups of patients have i) tumors which stain positively for E-cadherin or have an EGFR mutation(s) and ii) tumors which are negative for E-cadherin staining and EGFR mutation.

EGFR, epidermal growth factor receptor; p-EGFR, phosphorylated-EGFR; p-Akt, phosphorylated-Akt.

The current study warrants a larger one and presents an important question. We have six panels in Fig. 2, three of which showed significant differences and three of which did not. It is calculated that, if twice as many patients had been enrolled and had shown similar responsiveness and prognoses, all six sets of the two groups compared in Fig. 2 would have shown significant differences. To investigate this, a study should be scheduled where more than twice the number of patients is enrolled. We showed that tumors with a positive E-cadherin staining have a better prognosis after gefitinib therapy. It is, however, not clear whether the E-cadherin expression and EGFR mutation(s) contribute to it independently or synergistically. Basic and clinical researches addressing this issue may provide important information on the role of E-cadherin and EGFR in carcinogenesis.

Acknowledgements

We would like to thank Dr Yoshiaki Nagai, Department of Respiratory Medicine, Saitama Medical University, for his technical suggestions. We also thank Dr Yutaka Hatanaka, Dako, Japan, for his assistance in immunohistochemical analyses. This study was supported in part by a Grant-in-Aid from the Ministry of Education, Culture, Sports, Science and Technology of Japan and by a Grant-in-Aid from the Japan Society for the Promotion of Science.
