Abstract. Reactive oxygen species (ROS) cause oncogenic mutations through direct interaction with DNA. Carvedilol (CAR) exhibits antioxidative activity, and pre-clinical studies have identified that CAR may prevent malignant transformation in certain carcinogenic models. This suggests that CAR may be a potential agent in cancer prevention. In the present study, non-cancerous MCF-10A cells were used as a model to investigate the chemopreventive effect of CAR on benzo(a)pyrene (BaP)-induced cellular carcinogenesis. It was identified that CAR had the ability to eliminate BaP-induced ROS production and subsequent DNA damage. CAR/BaP activated the ROS-mediated phosphoinositide 3-kinase (PI3K)/protein kinase B (AKT)^{Thr308} signaling pathway, whereas the effectors of the PI3K/AKT signaling pathway, murine double minute 2 (MDM2) and p53^{Ser15}, served important functions in the BaP/CAR-mediated MCF10A cellular transformation. The results of the present study indicated that CAR may be a novel chemopreventive agent, notably in the prevention of estrogen receptor-negative breast cancer. The antioxidant effects of CAR may contribute to its chemopreventive activity.

Introduction

Cancer is a disease that is characterized by various stages, including initiation, promotion and progression. It is known that cancer cells are characterized by an increased rate of reactive oxygen species (ROS) production, which enhances the tumor metabolic adaptation, proliferation and survival. Excess ROS cause oncogenic mutations through direct reaction with DNA,

thus ROS are believed to be among the initiating insults that drive carcinogenesis (1). At the initial stage of breast cancer, increased ROS levels may promote cell susceptibility to DNA damage induced by environmental carcinogens, contributing to chromosome instability and cellular carcinogenesis (2). Thus, strategies and drugs that are designed to decrease ROS levels would be effective in preventing the initiation of breast cancer.

Carvedilol (CAR), a non-selective adrenergic blocker, was primarily designed to treat cardiovascular disease by inhibiting adrenergic receptors (3). Results from a pre-clinical study indicated that CAR could inhibit the proliferation of cancer cells and induce cell apoptosis *in vitro* (4). Our previous study identified that CAR significantly decreased the migratory and invasive capacities of breast cancer cells (5). Furthermore, a population-based cohort study indicated that long-term treatment with CAR was associated with a decreased risk of cancer, indicating that CAR may be a potential agent in the prevention of certain types of cancer (6). Results from a pre-clinical study suggested that CAR may prevent malignant transformation in *in vitro* and *in vivo* models of skin carcinogenesis (7). These results imply that CAR may be a novel chemopreventive agent.

MCF-10A cells are non-cancerous cells, which are transformable and form colonies in soft agar following exposure to tumor promoters (8). Benzo(a)pyrene (BaP) is able to transform MCF-10A cells into initiated breast cancer cells. This process is mediated via DNA adduct formation and ROS serve a crucial function in the initiation of carcinogenesis. Certain agents prevent tumorigenesis by their antioxidant activity (9). With the exception of the β -blocker effect, CAR exhibits antioxidant activity, but currently there is no knowledge of whether CAR is able to prevent breast cancer via oxidative resistance.

In the present study, non-cancerous MCF-10A cells were used as a model to investigate the chemopreventive effect of CAR on BaP-induced cellular carcinogenesis. The signaling pathways that were associated with CAR during the prevention of breast carcinogenesis were further investigated.

Materials and methods

Cells and reagents. Normal breast epithelial MCF-10A cells were purchased from the American Type Culture Collection

Key words: carvedilol, cancer prevention, reactive oxygen species, phosphoinositide 3-kinase/protein kinase B signaling pathway

(Manassas, VA, USA). BaP and CAR were purchased from Sigma; Merck KGaA (Darmstadt, Germany). These agents were prepared as 50 μM stock solutions and were stored at 4°C in double-distilled water. Phenol red-free Dulbecco's modified Eagle's medium (DMEM)/Ham's F12, horse serum, penicillin/streptomycin, antibiotic/antimycotic, epidermal growth factor, human insulin (Novolin R), trypsin-EDTA (10X), Hanks' balanced salt solution and PBS were purchased from Invitrogen; Thermo Fisher Scientific, Inc. (Waltham, MA, USA). Cholera enterotoxin was obtained from Enzo Life Sciences, Inc. (Farmingdale, NY, USA). AKT inhibitor VIII and AKT phosphorylation activator SC79 were purchased from MedChemExpress (Monmouth Junction, NJ, USA). The human 8-hydroxy-2-deoxyguanosine (8-OH-dG) ELISA kit was purchased from Cusabio Technology LLC (Houston, TX, USA). All other chemicals were purchased from Sigma-Aldrich; Merck KGaA.

Cell culture. MCF10A cells were maintained in complete medium (1:1 mixture of DMEM and Ham's F12), supplemented with mitogenic additives including 5% horse serum, 10 μM insulin, 0.5 ng/ml hydrocortisol, 20 ng/ml epidermal growth factor and 100 ng/ml cholera enterotoxin. The medium was also supplemented with 100 U/ml penicillin and 100 U/ml streptomycin. All cultures were maintained at 37°C under 5% CO₂.

Cell treatments and harvesting. BaP and CAR were initially dissolved in dimethylsulfoxide and subsequently in cell culture medium. All treatments were prepared and administered under low light conditions, prior to incubation at 37°C in a 5% CO₂ humidified incubator. MCF-10A cells were divided into three groups, namely BaP treatment, CAR/BaP co-treatment and control. The BaP group was treated with 1 $\mu\text{mol/l}$ BaP for 6, 12, 24 or 36 h. The CAR/BaP group was treated with 1 $\mu\text{mol/l}$ BaP in combination with 0.5, 1.0, 5.0 or 10 $\mu\text{mol/l}$ CAR. The control group was cultured without CAR or BaP. To determine the effect of H₂O₂, MCF-10A cells were cultured with H₂O₂ (200 $\mu\text{mol/l}$) and CAR (5 $\mu\text{mol/l}$) for 36 h. The cells were harvested by trypsinization at 6, 12, 24 or 36 h, and were suspended in PBS without Mg²⁺ or Ca²⁺. The cells were snap-frozen at -196°C in liquid N₂ until further use.

Determination of intracellular ROS levels. The cultures were labeled with 5 $\mu\text{mol/l}$ dichlorodihydrofluorescein diacetate for 1 h. ROS levels were detected using flow cytometry (BD Biosciences, Franklin Lakes, NJ, USA) and fluorescence microscopy (Nikon Corporation, Tokyo, Japan). The cells were trypsinized from the cultures and resuspended in PBS for analysis of ROS, using a 15 mW air-cooled argon laser at an excitation wavelength of 488 nm. Dichlorofluorescein fluorescence emission was determined using a 529 nm band pass filter. The mean fluorescence intensity of 2x10⁴ cells was quantified using Multicycle AV software (version 3.0; Phoenix Flow Systems, San Diego, CA, USA).

Single cell gel electrophoresis (comet assay). MCF-10A cells were exposed to BaP/CAR for 48 h (one cycle) and/or exposed for between 5 and 20 cycles to induce cellular carcinogenesis (10). Cultured cells were harvested as aforementioned.

The comet assay was performed according to a previously published protocol (9), and tail moment was the indicator of DNA damage. Tail moment is defined as the product of the tail length and the fraction of total DNA in the tail, which can be calculated using commercially available and public domain software (9). Data analysis was performed using Komet software (version 5.5; Andor Technology, PLC, Belfast, Northern Ireland, UK), and Kinetic Imaging (version 5.0; Kinetic Imaging Ltd., Wirral, UK).

ELISA detection of 8-OH-dG in MCF-10A cells treated with BaP/CAR. The three groups of cells, namely BaP (1 μM) treatment, CAR (5 μM)/BaP (1 μM) co-treatment and control, were plated in 6-well dishes at a density of 1x10⁶ cells/dish cultured for 24 h. The cells were trypsinized and resuspended in PBS. Subsequently, two freeze-thaw cycles were performed and the homogenates were centrifuged at 5,000 x g for 5 min at 4°C. The supernatant was removed and the 8-OH-dG levels were determined using the 8-OH-dG ELISA kit, according to the manufacturer's protocol. Absorbance was determined at 450 nm using Curve Expert Professional software (version 2.3.0; win.cutephp.com/curveexpert_professional_1996267) to create a standard curve. Results are expressed in ng/ml. Samples were assayed in a blind manner.

Western blot analysis. Cell lysates were prepared by washing cells with PBS and were incubated for 10 min at 4°C in modified radioimmunoprecipitation assay lysis buffer [50 mmol/l Tris/HCl, 150 mmol/l NaCl, 1% Triton X-100, 0.5% sodium deoxycholate, 25 $\mu\text{g/ml}$ leupeptin, 10 $\mu\text{g/ml}$ aprotinin, 2 mmol/l EDTA and 1 mmol/l sodium orthovanadate (Sigma; Merck KGaA)]. The cells were scraped from the plates and centrifuged at 5,000 x g for 20 min at 4°C, and the supernatants were collected. The protein concentration levels were determined using a Bicinchoninic Acid assay kit (Pierce; Thermo Fisher Scientific, Inc.), and 40 μg whole cell lysates were separated by SDS-PAGE (10% gels). The samples were transferred onto a nitrocellulose membrane by wet blotting. The membrane was blocked with 5% fat-free dry milk in PBS for 1 h at room temperature, and incubated with primary antibodies overnight at 4°C. The antibodies used were anti-phospho (p)-AKT (Thr³⁰⁸) (1:400; cat. no. 558316; BD Biosciences), anti-murine double minute 2 (MDM2; 1:400; cat. no. 556353; BD Biosciences), anti-p-p53 (Ser¹⁵/Ser²⁰) (1:100; cat. no. sc-10176; Santa Cruz Biotechnology, Inc., Dallas, TX, USA) and anti- β -arrestin (1:100; cat. no. sc-21872; Santa Cruz Biotechnology, Inc.). Following three washes with PBS, the membrane was incubated with goat anti-mouse immunoglobulin G (IgG) (1:8,000; cat. no. 31430; Thermo Fisher Scientific, Inc.) and goat anti-rabbit IgG (1:8,000; cat. no. 31460; Thermo Fisher Scientific, Inc.) secondary antibodies and visualized with SuperSignal West Dura Extended Duration Substrate (Thermo Fisher Scientific, Inc.).

Statistical analysis. Unless indicated otherwise, each assay was conducted three times. Results are presented as the mean \pm standard error of the mean. Results were analyzed by one-way analysis of variance or Student's t-test; multiple comparisons between the groups were performed using the

Figure 1. CAR inhibits BaP-induced ROS generation. MCF-10A cells were exposed to BaP (1 μ M) with or without CAR (1, 5 or 10 μ M) for 24 h and the cells were labeled with dichlorodihydrofluorescein diacetate (5 μ M). The images were obtained by fluorescence. CAR, carvedilol; BaP, benzo(a)pyrene; ROS, reactive oxygen species.

Student-Newman-Keuls method. $P < 0.05$ was considered to indicate a statistically significant difference.

Results

CAR inhibits BaP-induced ROS production. BaP induces DNA damage through the generation of ROS, which initiate oxidative damage to nucleic acids (2). In addition to the β -blocker effect, CAR acts as an antioxidant and a ROS scavenger (11). MCF-10A cells were used in order to investigate the effects of CAR on BaP-mediated ROS production. In the absence of BaP, MCF-10A cells generated ROS spontaneously, and CAR had the potential to decrease ROS production in cells that were not treated with BaP (Fig. 1). BaP increased ROS production in MCF-10A cells; however, CAR, at concentrations $\geq 1 \mu$ M, attenuated BaP-induced ROS production in a dose-dependent manner (Fig. 2, upper panel). Short-term exposure (6 h) of MCF-10A cells to 1 μ M BaP induced ROS, and ROS production reached a peak at 24 h (Fig. 2, lower panel). BaP induced a significant increase in ROS levels in a time-dependent manner (between 6 and 24 h), although ROS levels decreased at 36 h, indicating endogenous adjustment (Fig. 2). Co-treatment of CAR and BaP decreased BaP-induced ROS production at all time points investigated in a dose-dependent manner (CAR concentration $\geq 1 \mu$ M) (Figs. 1 and 2).

CAR eliminates BaP-induced DNA damage. BaP induced significant DNA damage as demonstrated using the alkaline comet assay in MCF-10A cells. Exposure of the cells to BaP for 5 cycles was sufficient to induce DNA strand breaks in MCF-10A cells, although no DNA damage was observed in the 15-20 exposure cycles using the alkaline comet assay.

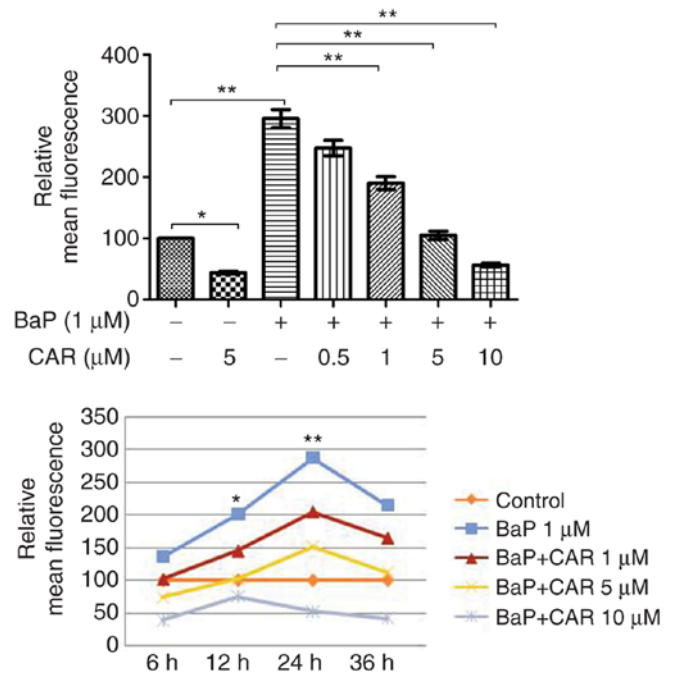

Figure 2. Fluorescence intensity of ROS was determined in MCF-10A cells treated with BaP and/or CAR using flow cytometry. Results are expressed as the mean \pm standard deviation of three independent experiments. * $P < 0.05$, ** $P < 0.01$ vs. BaP treatment for 6 h. CAR, carvedilol; ROS, reactive oxygen species; BaP, benzo(a)pyrene.

Treatment of the cells with 1 μ M BaP caused DNA damage at 12, 24 and 36 h of culture, compared with control cells; however, CAR attenuated DNA strand breaks that were induced by BaP (Fig. 3A). A concentration-dependent effect

Figure 3. CAR decreases BaP-induced DNA strand breaks and 8-OH-dG concentration. MCF-10A cells were treated with BaP (1 μ M) and CAR (1, 5 and 10 μ M) for different durations. (A) DNA damage was analyzed using the comet assay. The results present the mean olive tail moment, an indicator of DNA damage, \pm standard error of the mean for 100 cells ($n=3$). (B) 8-OH-dG was detected using ELISA in cells treated with 1 μ M BaP with or without 10 μ M CAR. * $P<0.05$, ** $P<0.01$. BaP, benzo(*a*)pyrene; 8-OH-dG, 8-hydroxy-2-deoxyguanosine; CAR, carvedilol.

Figure 4. CAR decreases BaP-induced DNA strand breaks in MCF-10A cells as determined using the comet assay. Cells were cultured with 1 μ M BaP for 24 h and exhibited apparent DNA damage. CAR and AKT inhibitor VIII eliminated DNA damage caused by BaP. Blue (excitation, 330 nm; emission, 420 nm) indicates nuclei (DAPI staining). CAR, carvedilol; BaP, benzo(*a*)pyrene; AKT, protein kinase B.

was observed using CAR. Treatment of the cells with 10 μ M CAR and BaP for 24 h attenuated 68% of BaP-induced DNA damage (data not shown), which corresponded nearly to the levels of the control group (Fig. 3A). As a marker of DNA oxidative damage, 8-OH-dG levels increased in MCF-10A cells treated with BaP determined using the 8-OH-dG ELISA kit, although CAR reversed the effect of BaP (Fig. 3B). Cells cultured with 1 μ M BaP for 24 h exhibited apparent DNA damage, and CAR and AKT inhibitor VIII eliminated DNA damage caused by BaP (Fig. 4). These results indicated that CAR has the ability to inhibit BaP-induced DNA damage.

CAR inhibition of BaP induces the PI3K/AKT signaling pathway via the decrease in ROS production. Certain carcinogens induce intracellular ROS accumulation, and increase the expression of PI3K and AKT proteins. ROS also directly activate PI3K, and activated PI3K further phosphorylates its downstream target AKT. The alterations in the PI3K/AKT signaling pathway have been revealed to promote cell survival and proliferation (12,13). In order to investigate the mechanism of CAR suppression in BaP-induced MCF-10A cell carcinogenesis, the level of expression and phosphorylation of target proteins associated with the PI3K/AKT signaling pathway was determined. Western blot analysis using an antibody against p-(activated) AKT^{Thr308} indicated that, compared with untreated cells, p-AKT^{Thr308} expression was increased significantly in MCF-10A cells that were treated with BaP. When cells were incubated with CAR (5 μ M) and BaP simultaneously for various durations, p-AKT^{Thr308} expression decreased in all cases (Fig. 5A). These results suggested that AKT phosphorylation induced by BaP could be inhibited by CAR in MCF-10A cells. However, AKT (non-phosphorylated) expression was

not influenced by treatment with BaP and CAR for 24 h (Fig. 5B). However, in the absence of BaP, MCF-10A cells were co-cultured with H₂O₂ and CAR, and p-AKT^{Thr308} expression increased markedly (data not shown). These results indicated that CAR inhibited BaP-induced PI3K/AKT activation via the inhibition of ROS generation, but not ROS scavenging.

CAR inhibition of BaP causes a change in MDM2 and p53 expression levels. MDM2 is an important AKT substrate. Phosphorylation of MDM2 by AKT can target the tumor suppressor p53 for degradation through ubiquitination. p53 modulates cells that are under oxidative stress and aids the adaptation of the cell's oxidative mechanism to the remodeled redox balance, thus preventing oxidative damage to DNA and proteins (14,15). Therefore, the effect of CAR on the expression of p53^{Ser15}, p53^{Ser20} and MDM2 in BaP-induced cells was investigated by western blotting. As CAR suppresses BaP-induced neoplastic activity and associated protein function at concentrations between 1 and 10 μ M, 5 μ M CAR was used as the optimal concentration. It was identified that MDM2 expression was upregulated in BaP-treated cells, although CAR was able to eliminate the effects of BaP (Fig. 5C). In addition, the expression of p53^{Ser15} was downregulated in BaP-treated cells, although CAR could prevent the influence

Figure 5. Cell lysates were prepared and analyzed by western blotting to determine the levels of (A) AKT^{Thr308}, (B) AKT and (C) MDM2, with GAPDH used as a control. The levels of pAKT^{Thr308}, MDM2, p53^{Ser15} and GAPDH were quantified by densitometry. All results are representative of three independent experiments. *P<0.05, **P<0.01. AKT, protein kinase B; MDM2, murine double minute 2; BaP, benzo(a)pyrene; CAR, carvedilol.

Figure 6. Cell lysates were prepared and analyzed by western blotting to determine the levels of (A) p53^{Ser15} and (B) p53, with GAPDH used as a control. The levels of p53^{Ser15} and GAPDH were quantified by densitometry. All results are representative of three independent experiments. *P<0.05, **P<0.01. Cells were cultured with and without CAR/SC79 for 24 h, and cell lysates were prepared and analyzed by western blotting to detect the levels of (C) MDM2 and (D) p53^{Ser15}, with GAPDH as a control. CAR, carvedilol; MDM2, murine double minute 2; BaP, benzo(a)pyrene; AKT, protein kinase B; B+C, BaP and CAR.

of BaP, and eliminate these changes caused by BaP at the time points investigated (Fig. 6A). However, p53^{Ser20} expression did not alter in BaP-treated cells (data not shown). Furthermore, p53 (non-phosphorylated) expression was not influenced when cells were treated with BaP and CAR for 24 h (Fig. 6B). As

effectors of the PI3K/AKT signaling pathway, the MDM2 and p53^{Ser15} proteins serve important functions in the effects of BaP/CAR on MCF-10A cell transformation.

When MCF-10A cells were co-cultured with BaP and the AKT inhibitor VIII, BaP had no influence on

MDM2 expression and p53 degradation (Figs. 5C and 6A). Furthermore, BaP-induced DNA damage was counteracted by the AKT inhibitor VIII as demonstrated using the alkaline comet assay (Fig. 4). In contrast with the inhibition of AKT, when cells were treated with CAR and SC79 (an AKT phosphorylation activator), enhanced MDM2 expression and p53 degradation were evident from western blot analysis (Fig. 6C and D). CAR was not able to inhibit the effects of SC79, which indicated that CAR acts upstream of the PI3K/AKT signaling pathway. These data indicated that BaP-induced ROS production activated PI3K/AKT, which in turn upregulated MDM2, thus facilitating p53 degradation. CAR prevents cellular carcinogenesis induced by BaP via the suppression of PI3K/AKT and MDM2 activity, which increases p53 levels in MCF-10A cells.

Discussion

ROS are free radicals with marked oxidative activity. ROS oxidize proteins and DNA, and damage various cellular organelles. This initiates the cellular injury responsible for aging and disease (16). ROS-mediated DNA damage can promote the malignant transformation of cells, and facilitate cell survival and proliferation (17-20). Increases in ROS may promote cell susceptibility to DNA damage induced by carcinogens, contributing to cellular carcinogenesis (21). However, the exact function of ROS in BaP-induced carcinogenesis of breast pre-cancerous cells is unclear.

CAR is a non-selective adrenergic blocker, primarily designed to treat cardiovascular disease by blocking adrenergic receptors. CAR is licensed by the US Food and Drug Administration for the treatment of chronic heart failure partly due to its antioxidant and ROS-scavenging properties (22). In addition, CAR has the potential of anti-neoplastic action, including breast cancer and glioma (4). In our previous study, we identified that CAR could inhibit migration and invasion of several breast cancer cell lines (5). A recent study indicated that CAR could prevent skin carcinogenesis induced by DMBA (7). However, there are no studies regarding the potential prevention of breast cancer by CAR. To address this question and to investigate the mechanisms of CAR in eliminating the activity of BaP in cellular carcinogenesis, CAR activity in the modulation of BaP-induced increases in ROS, DNA damage, and associated signaling pathways in pre-cancerous breast cells were determined.

It was identified that BaP induced a significant and sustained increase in ROS levels in MCF-10A cells, and that CAR attenuated BaP-induced ROS production in a concentration-dependent manner at doses $\geq 1 \mu\text{M}$. Furthermore, CAR was able to decrease ROS production in MCF-10A cells that were not treated with BaP, since the cells could generate ROS spontaneously. ROS are associated with clustered DNA damage, chromosomal aberrations and induction of carcinogenesis in normal breast cells (23). The alkaline comet assay and 8-OH-dG ELISA kit were used to investigate the detection of DNA damage. The data demonstrated that BaP induced significant DNA damage, and that CAR could attenuate DNA strand breaks induced by BaP at the time points investigated. Compared with low-dose CAR treatment, the tail moment was lower in the high-dose CAR groups. In the present study,

exposure of MCF-10A cells to $1 \mu\text{M}$ BaP for 5 cycles was identified to be sufficient to induce DNA damage. However, no DNA damage was detected by the alkaline comet assay and 8-OH-dG detection, when cells were exposed to BaP for 10-20 cycles. It was identified that the single treatment of MCF-10A cells with a high concentration of BaP for 48 h was sufficient to cause chromosomal aberrations (24). Thus, we hypothesized that MCF-10A cells treated with BaP for >10 cycles may progress to cancerous cells, whereas BaP exhibited no effects on the cancer cells. The investigation of the malignant transformation of the cells requires further investigation.

Alterations in the PI3K/AKT pathway have been observed in various types of tumor (25). Pre-cancerous cells chronically exposed to carcinogens increase their ROS production, which mediates the activation of PI3K, AKT and target proteins, resulting in increased cell proliferation and anchorage-independent growth (12). The aforementioned results led to the investigation of whether the PI3K/AKT signaling pathway may be involved in breast carcinogenesis induced by BaP. Phosphorylation at Thr³⁰⁸ and/or Ser⁴⁷³ indicates the activation of AKT (26). Vincent *et al* (27) hypothesized that the phosphorylation of Thr³⁰⁸ is a more reliable biomarker for the activity of AKT compared with phosphorylation of Ser⁴⁷³. In the present study, it was identified that chronic exposure to BaP could induce AKT^{Thr308} phosphorylation in MCF-10A cells, although the function of BaP was inhibited by CAR via inhibition of ROS production. In contrast with BaP, H₂O₂ treatment of cells led to AKT activation, and CAR had no influence. This suggested that CAR inhibited BaP-induced PI3K/AKT activation through the inhibition of ROS generation, but not through ROS scavenging. The p53 gene may lose its repair activity and permit passage of DNA mutations from one generation to the next. This increases the risk of cell carcinogenesis to stress and damage. MDM2 is a downstream substrate of PI3K/AKT and degrades p53 to promote tumorigenesis (28). Following DNA damage, p53 can be activated, leading to the repair of DNA damage (29). The ability of PI3K/AKT activation to increase DNA damage by carcinogens in MCF-10A cells led us to hypothesize that BaP/CAR may affect the ability of MDM2 and p53. The results of the present study indicate that BaP could not increase the levels of p53 in MCF-10A cells. A possible reason may be that increased ROS induced by BaP activate AKT and subsequent MDM2, and activated MDM2 degrades p53 by ubiquitination in MCF-10A cells. The lack of p53 response by BaP in MCF-10A cells suggested that p53 had no protective functions on DNA damage in these cells; this may, in part, contribute to the potent mammary carcinogenicity of BaP. However, in the presence of CAR or AKT inhibitor VIII, the expression of p53 in MCF-10A treated with BaP was unknown. Generally, Ser¹⁵ and Ser²⁰ in p53 are typically phosphorylated with DNA damage, and Ser¹⁵ is the most common site of phosphorylation (30-32). Therefore, antibodies against p-p53 at Ser¹⁵ and Ser²⁰ to detect p53 activity by western blotting. It was identified that p-p53^{Ser15} expression, but not p-p53^{Ser20}, was upregulated in the presence of CAR or AKT inhibitor VIII in MCF-10A cells treated by BaP. This suggests that AKT activity (caused by ROS/BaP) was inhibited by CAR or AKT inhibitor VIII, subsequent

MDM2 phosphorylation by p-AKT did not occur. Therefore, p53^{Ser15} protein could not be degraded by MDM2 through ubiquitination.

Mitogen-induced activation of PI3K and its downstream target, AKT, results in phosphorylation of MDM2 on Ser¹⁶⁶ and Ser¹⁸⁶. Phosphorylation of these residues is necessary for translocation of MDM2 from the cytoplasm into the nucleus (28). Mutation of the AKT phosphorylation sites in MDM2 produces a mutant protein that is unable to enter the nucleus and increases p53 activity (28). Zhou *et al* (33) reported that AKT physically associates with MDM2 and phosphorylates it at Ser¹⁶⁶ and Ser¹⁸⁶. Phosphorylation of MDM2 enhances its nuclear localization and increases p53 degradation (33). The results of the present study identified that MDM2 expression was upregulated, although without detection of p-MDM2, as the downstream target of PI3K, phosphorylation of MDM2 by activated AKT is highly likely. Thus, increased MDM2 expression or phosphorylated MDM2 enhanced p53 degradation and may induce carcinogenesis in MCF10A cells. The results concerning the PI3K/AKT/MDM2 signaling pathway provided sufficient evidence for the function of CAR in the prevention of breast tumorigenesis.

Chemoprevention has become an important approach for decreasing breast cancer morbidity and mortality (34). Tamoxifen and raloxifene are the classical chemopreventive drugs used to prevent estrogen receptor (ER)-positive breast cancer that have minimal effects on ER-negative breast cancer (34). The results of the present study indicate that CAR may be considered a novel chemopreventive agent, notably in the prevention of ER-negative breast cancer, since MCF-10A cells rarely express ER (35). The antioxidant effect of CAR may contribute to its cancer-preventive activity. Although the present study focused on breast cancer prevention, the results may lay the foundation for clinical trials that can be designed to prevent other types of cancer, as reported recently in the prevention of hepatocarcinogenesis (36).
