Abstract. Platinum-based antitumor agents have been widely used to treat head and neck squamous cell carcinoma (HNSCC) and numerous other malignancies. Cisplatin is the most frequently used platinum-based antitumor agent, however drug resistance and numerous undesirable side effects limit its clinical efficacy for cancer patients. Cancer cells discharge cisplatin into the extracellular space via copper transporters such as ATPase copper transporting beta (ATP7B) in order to escape from cisplatin-induced cell death. In the present study, it was demonstrated for the first time that the copper chelator ammonium tetrathiomolybdate (TM) has several promising effects on cisplatin and HNSCC. First, TM suppressed the ATP7B expression in HNSCC cell lines in vitro, thereby enhancing the accumulation and apoptotic effect of cisplatin in the cancer cells. Next, it was revealed that TM enhanced the antitumor effect of cisplatin in HNSCC cell tumor progression in a mouse model of bone invasion, which is important since HNSCC cells frequently invade to facial bone. Finally, it was demonstrated that TM was able to overcome the cisplatin resistance of a human cancer cell line, A431, via ATP7B depression in vitro.

Introduction

Head and neck squamous cell carcinoma (HNSCC) is a common malignant tumor (1,2). Despite advances in the early detection, diagnosis, and management of HNSCC, the long-term survival rate of HNSCC patients has improved only marginally over the past decades, and more effective strategies for the treatment of HNSCC are thus required (3). Although immunotherapy with anti-programmed cell death protein 1 (anti-PD-1) and therapy with anti-epidermal growth factor receptor (anti-EGFR) were recently approved in many countries for the treatment of HNSCC patients, cisplatin is still the most widely used antitumor drug for HNSCC (4-6).

First synthesized in 1844 (7), cisplatin, or cis-diamminedicloroplatinum (II), is a metallic (platinum) coordination compound with a square planar molecular geometry. Cisplatin is activated via the replacement of a chloride ligand with H₂O in the cancer cell cytoplasm. Activated cisplatin binds to the N7 atom of guanines in DNA, which in turn generates intra-strand DNA crosslinks (ICLs) (8). ICLs are cytotoxic lesions with a covalent linkage between opposite strands of double-stranded DNA. ICLs lead to defects of vital DNA metabolic processes such as transcription and DNA replication in cancer cells, resulting in cancer cell death (9). HNSCC patients usually exhibit a good response to cisplatin chemotherapy however later relapse, since the development of cisplatin resistance markedly reduces the clinical effectiveness of this agent (10). Some research indicates that cisplatin resistance can result from variations of genetic and protein expression at the cellular level (11,12). Another mechanism of cisplatin resistance consists of reducing the cellular accumulation of cisplatin by increasing its efflux and suppressing its influx (13). It was revealed that the copper transporter ATP7B (ATPase copper transporting beta) is linked to cisplatin efflux from cancer cells (14). Copper transporter expression...
is closely linked to the serum copper concentration (15). The copper chelator ammonium tetrathiomolybdate (TM) may be effective for the treatment of copper metabolism disorder and Wilson's disease (16). We previously demonstrated that copper chelators have a bone-protective effect against bone-invasive HNSCC cells (17), however, the potential influence of TM on the accumulation of cisplatin in cancer cells in HNSCC is not clear. The present findings provide the first evidence that the copper chelator TM enhances the antitumor effect of cisplatin via ATP7B suppression in an HNSCC mouse model.

Materials and methods

Reagents. SLC31A1/CTR1 antibody (anti-rabbit, polyclonal; cat. no. GTX48534) was purchased from GeneTex. ATP7A (anti-rabbit, polyclonal; ID product code ab125137) was purchased from Abcam. ATP7B (anti-rabbit, polyclonal; cat. no. NB100-360) was purchased from Novus Biologicals. Cleaved caspase-3 (Asp175) (5A1E) (anti-rabbit, monoclonal; product no. 9664), Ki-67 (D2H10) (anti-rabbit, monoclonal; product no. 9027), and horseradish peroxidase (HRP)-conjugated IgG antibody (goat anti-rabbit, monoclonal; product no. 7074) were purchased from Cell Signaling Technology, Inc.

Cell lines and culture conditions. The human oral squamous cell carcinoma lines HSC-2 (#JCRB0622), HSC-3 (#JCRB0623), and HSC-4 (#JCRB0624) and the human skin squamous cell carcinoma line A431 (#JCRB004) were obtained from the Human Science Research Resources Bank (Osaka, Japan). All cell lines were cultured in Dulbecco's modified Eagle's medium (DMEM) (Thermo Fisher Scientific, Osaka, Japan). All cell lines were cultured in an atmosphere of 10% CO2 at 37˚C. The cisplatin concentrations (IC50) were cultured for 24 h. Cells were washed and fixed, then incubated with Annexin V–FITC and PE (cat. no. 88-8005-72, cat. no. 00–6990; eBioscience; Thermo Fisher Scientific, Inc.). After staining, the cells were washed, suspended in the FACS staining buffer, and analyzed on a FACS Aria III flow cytometer using FlowJo. Ver.10 (both from BD Biosciences).

Real-time PCR analysis. Total RNA from cells was extracted using RNA easy Mini kit (Qiagen Sciences, Inc.). cDNA synthesis was performed with 1 μg of total RNA using PrimeScript (Takara Bio, Inc.). Real time PCR analysis was carried out with iQ SYBR Green Mix using the CFX Connect Real-Time PCR Detection System (Bio-Rad Laboratories, Inc.). Detection was carried under following cycle conditions. Initial denaturation at 95˚C for 30 sec, followed by 41 cycles of 95˚C for 10 sec and 60˚C for 35 sec.

The primer sequence for ATP7B was forward, 5′-GCC TTA TAC TAT GTC TGG TCA-3′ and reverse, 5′-TTG AAG GTA TCA ATG ACG GCC TCT-3; and for ATP7A, forward, 5′-GCC ATT GCA GAA GGA AAG-3′ and reverse, 5′-TGA TAA ACA AGA AAT CTG GCA CCA CAC CTT-3 and for GAPDH, forward, 5′-GAA GTG ATG ACG GCC TCT-3 and reverse, 5′-GAT TTCAGGTA GGTTCGGTAG-3′.

The relative fold change values were evaluated by normalization to β-actin expression via the 2ΔΔCq method (20).

Cell proliferation assay. The HSC-2 and HSC-3 cells were each plated in six-well plates at a density of 1x10^4 cells/well. Two 6-well plates, one for each cell line, were used for each of the four groups: A control, cisplatin-treated, TM-treated, and cisplatin+TM-treated group. After 72 h, the cells were counted using a TC20 automated cell counter (Bio-Rad Laboratories, Inc.).

Immunocytochemical analysis. HSC-3 cells were plated on culture slides (BD Falcon; BD Biosciences) at a density of 1x10^3 cells/well. After cisplatin or TM treatment, the number of apoptotic cells was assessed by the DeadEnd™ Fluorometric TUNEL System (Promega, Corporation).

Cisplatin concentration assay. The cisplatin concentrations in the cell suspensions were measured by a cisplatin assay kit (MicroMolar Cisplatin Assay Kit; ProFoldin). The samples, buffer, and chelate color solution were mixed and incubated for 95˚C for 5 min. The samples were electrophoresed in 4-12% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) gels, and the proteins were transferred onto polyvinylidene difluoride (PVDF) membranes (Bio-Rad Laboratories, Inc.) and blocking with 5% skim milk for 1 h. The membranes were incubated with primary (4˚C, for 24 h) and secondary (room temperature, for 1 h) antibodies according to the ECL chemiluminescence protocol (product no. RPN2109; Amersham Biosciences; GE Healthcare Life Sciences) to detect secondary antibody binding. Antibodies against ATP7A (1:1,000), ATP7B (1:1,000), CTR1 (1:1,000), caspase-3 (1:1,000), cleaved caspase-3 (1:1,000), β-actin (1:10,000) and GAPDH (2,000) were used as primary antibodies. HRP-conjugated anti-rabbit antibody (1:2,000) was used as the secondary antibody. A ChemiDoc MP system (Bio-Rad Laboratories, Inc.) was used for the analysis of western blots.

Flow cytometric analysis. HSC-3 cells were treated with cisplatin with or without TM for 24 h. Cells were washed and fixed, then incubated with Annexin V–FITC and PE (cat. no. 88-8005-72, cat. no. 00–6990; eBioscience; Thermo Fisher Scientific, Inc.). After staining, the cells were washed, suspended in the FACS staining buffer, and analyzed on a FACS Aria III flow cytometer using FlowJo. Ver.10 (both from BD Biosciences).
60 min at 65˚C. The absorbance was then read at a wavelength of 535 nm using a microplate reader (SH-1000; Hitachi).

**Animal experiments.** A mouse model of bone invasion by human oral squamous cell carcinoma was established in 5-week-old male BALB/c nude mice (n=6 per group; n=24 total; mean body weight, 19.5 g; Charles River Laboratories) by i.p. inoculation of 1x10⁵ HSC-3 cells into the bone marrow space of the right tibial metaphysis under general anesthesia with 0.4 mg/kg of medetomidine, 4.0 mg/kg of midazolam and 5.0 mg/kg of butorphanol. Mice were maintained in SPF cages. Body condition scoring was applied and body weight was monitored daily. At 7 days after the tumor cell inoculation, the mice were divided into four groups (control, cisplatin-treated, TM-treated, and cisplatin+TM-treated). The cisplatin group was treated with a single intraperitoneal injection of 100 µl of cisplatin (5 mg/kg). The TM group was orally administered 200 µl of a solution containing TM (1 mg) in phosphate-buffered saline (PBS) 5x/week for 2 weeks. The cisplatin+TM-treated group was treated with both agents at the doses used in the cisplatin group and TM group. At the end of the experimental period (day 35), the mice were sacrificed with cervical dislocation by formal trained researcher under anesthesia with 0.4 mg/kg of medetomidine, 4.0 mg/kg of midazolam and 5.0 mg/kg of butorphanol (i.p) and the right tibias of the nude mice that had been injected with the cancer cells were excised and then fixed in 4% paraformaldehyde phosphate buffer solution. There were no differences in body weight in the control (24.9 g), cisplatin (24.1 g), TM (24.5 g) and dual-treated group (23.9 g) at the end of the experiment. The criteria of humane endpoints for euthanasia was loss of >20 percent of body weight compared to the age-matched controls. Death of the animal was verified by cessation of cardiovascular and respiratory movements. All of the animal experimental protocols were approved by the Ethics Review Committee for Animal Experimentation of the Okayama University Graduate School of Medicine and Dentistry (approval no. OKU-2018663).

**In vivo radiography and assessment of osteolytic lesion areas.** Osteolytic bone destruction in the mice was assessed on radiographs. The bones were placed against films (22x27 cm; Fuji Industrial Film FR; Fuji Photo Film) and exposed to soft X-rays at 35 kV for 15 sec with the use of a Sofron apparatus (Sofron). The radiolucent bone lesions were observed microscopically (IX81; Olympus Corporation), and the areas were quantified with Lumina Vision/OL image software (Mitani Corporation). A micro-CT image was obtained with a SKYSCAN scanner (Bruker Japan).

**Immunohistochemical analysis.** Each tibial bone was fixed in 10% formalin at room temperature for 48 h, decalcified, and then embedded in paraffin. Serial sections were then prepared (5 µm-thick). The specimens were incubated with ATP7B (1:250), Ki-67 (1:250) or IL-6 (1:100) antibodies overnight at 4˚C, followed by Alexa Fluor 488 anti-rabbit IgG.

(1:1,000) as a secondary antibody. Nuclei were counterstained with Fluoroshield mounting medium with DAPI (product no. ab104139; Abcam).

Statistical analysis. The data were analyzed using an unpaired Student’s t-test for comparisons of two groups and by performing a one-way analysis of variance (ANOVA) and a post hoc Bonferroni or Dunnett’s test for multiple group comparisons. Graph Pad Prism, ver. 7.0 (GraphPad Software, Inc., La Jolla, CA, USA) was used for all analyses. The results are expressed as the mean ± standard deviation (SD). Probability (P)‑values <0.05 were considered to indicate a statistically significant difference.

Results

ATP7B expression in the human HNSCC tissue. Fig. 1A provides a representative histological pattern of normal oral tissue and HNSCC tissue. ATP7B was expressed significantly higher in the HNSCC samples compared to the normal epithelium samples (P<0.0001) (Fig. 1B). To determine whether HNSCC cells expressed ATP7B in vitro, western blot analysis was performed in HSC-2, HSC-3 and HSC-4 cells. As revealed in Fig. 1C, the results of the western blot analysis revealed a high expression of ATP7B in the HNSCC cells. CTR1 is a cisplatin influx transporter. The human head and neck carcinoma cell line HSC-3 markedly expressed CTR1. Thus, HSC-3 cells were used for the subsequent experiment.

TM enhances the antitumor effect of cisplatin on oral squamous cell carcinoma cells. The effect of TM on the expression of the cisplatin efflux transporter ATP7B was then assessed in HNSCC cells by western blotting, immunocytocchemical analysis and Real-time PCR. First, TM was added to an HSC-3 culture medium for 24 h, and as revealed in Figs. 2A and S1, the protein expression of ATP7B in the TM-treated HSC-3 cells was decreased by 40%, while the mRNA expression of ATP7B in the TM-treated HSC-3 cells was not altered. Next, immunocytocchemical analysis was performed, and the results indicated that ATP7B expression in the cell membrane was decreased by TM treatment, confirming the results of the western blotting (Fig. 2B).

Figure 2. Effect of TM on ATP7B expression and the synergistic antitumor effect of cisplatin in HNSCC cell proliferation in vitro via cisplatin accumulation. HSC3 cells were plated in triplicate and treated with 5 µM TM for 24 h. (A) The expression of ATP7B in control HSC-3 cells and TM-treated HSC-3 cells was analyzed based on the image blot density revealed by western blotting. (B) Immunofluorescence analysis of ATP7B and DAPI in the cells. Upper images, ATP7B (green); middle images, DAPI (blue); lower images, merged. Sections were incubated with rabbit anti-ATP7B (1:100), then with Alexa Fluor 488 anti-rabbit IgG (1:1,000) and encapsulated with DAPI. (C) The cisplatin concentration in HSC-3 cells was evaluated after 6-h cisplatin treatment with or without 24-h TM pre-incubation. (D) Antitumor and synergistic antitumor effect of TM against HSC-3 HNSCC cells. HSC-3 cells were treated with cisplatin with or without TM for 24 h. Live cells were counted with trypan blue reagent. Data represent the relative ratio (the control is indicated as 1.0). *P<0.05 cisplatin + TM group vs. the cisplatin treated group. TM, tetrathiomolybdate; ATP7B, ATPase copper transporting beta; HNSCC, head and neck squamous cell carcinoma.
Based on these data, it was hypothesized that TM may enhance the antitumor effect of cisplatin in HNSCC cells via an accumulation of cisplatin. It was therefore evaluated whether TM increased the cisplatin accumulation in the HNSCC cell lines, by performing a platinum assay. As revealed in Fig. 2C, the cisplatin concentration in the HSC‑3 cells was increased by pretreatment with TM. Next, to analyze the additive antitumor effect of TM and cisplatin against HNSCC cells in vitro, a trypan blue staining assay was performed. As revealed in Fig. 2D, TM did not affect the number of viable HSC‑3 cells up to 48 h after treatment compared with the control. Cisplatin decreased the proliferation of HSC‑3 cells compared with the control group. Notably, the TM+cisplatin dual treatment significantly decreased the cell proliferation compared to the single treatment of cisplatin. The antitumor effect of cisplatin consists of inducing apoptosis by DNA cross-linking in cancer cells. The cleavage of caspase‑3 is well known as an indicator of apoptosis. The effect of TM on cisplatin‑induced cleavage of caspase‑3 was therefore assessed by performing a western blot analysis. As revealed in Fig. 3A, TM and cisplatin did not affect the expression of total caspase‑3. Furthermore, TM did not directly induce the cleavage of caspase‑3. However, TM enhanced the cisplatin‑induced cleavage of caspase‑3. Moreover, TM enhanced the cisplatin‑induced DNA fragmentation as evaluated by fluorescence

Figure 3. Apoptosis effects of TM and cisplatin on HNSCC cells grown in vitro. (A) The expression of total and cleaved caspase‑3 in HSC‑3 cells treated with or without cisplatin and TM. Total and cleaved caspase‑3 in HSC‑3 cells was evaluated based on the image blot density revealed by western blotting. (B) Immunofluorescence analysis of Tunnel and DAPI in the HSC‑3 cells. Upper images, Tunnel (green); middle images, DAPI (blue), lower images, merged. (C) Flow cytometric analysis: Propidium iodide (PI) and Annexin V staining of HSC‑3 cells treated with cisplatin or with cisplatin+TM for 24 h. Apoptotic cells were evaluated with FACS Aria III. TM, tetramethylthiopyridate; HNSCC, head and neck squamous cell carcinoma. Data are expressed as the mean ± SD. *P<0.05. Cisplatin+ TM‑treated vs. cisplatin‑treated cells.
tunnel staining assay (Fig. 3B). Flow cytometric analysis was also performed to evaluate the effect of TM on cisplatin-induced HNSCC apoptosis. The plots of Annexin V/FITC-A vs. propidium iodide-A from the gated cells revealed the populations corresponding to viable and non-apoptotic (Annexin V−/PI−) and (Annexin V+/PI+, Annexin V+/PI+) apoptotic cells. TM did not directly induce apoptosis of HSC-3 cells (control 29.8%, TM 37.0%). However, TM significantly enhanced the effect of
cisplatin-induced apoptosis (cisplatin 40.3%, cisplatin with TM 52.2%) (Fig. 3C).

**TM enhances the anticancer effect of cisplatin and bone resorption in vivo.** To analyze the dual treatment effect of TM+cisplatin in vivo, an HNSCC bone invasion mouse model was established using HSC-3 cells. The mice were administered TM (1 mg/kg) and/or a low dose cisplatin (5 mg/kg) 5x/week beginning 7 days after the tumor inoculation, and the tumor volume was measured on day 35. The dual treatment effect of TM+low-dose cisplatin on osteolytic bone destruction induced by oral squamous carcinoma was determined by conducting soft X-ray and micro-CT examinations. As revealed in Fig. 4A and B, the osteolytic lesions were clearly visible in the tibiae of the mice with bone invasion induced by HSC-3 cells treated with the vehicle (control) only. The use of TM or low-dose cisplatin alone tended to suppress the osteolytic bone destruction and tumor burden in the bone marrow. Notably, few destructive lesions were detected in the tibiae of the mice treated with TM+low-dose cisplatin. The total area of radiographic osteolytic lesions from all tibiae was significantly suppressed by the TM+cisplatin treatment compared to treatment with cisplatin treatment (P<0.05). Hematoxylin and eosin (H&E) staining revealed tumor growth in bone marrow.

The dual treatment with TM+cisplatin markedly decreased the tumor burden (Fig. 4C). Morisawa et al demonstrated that TM has an anti-bone resorption effect by suppressing osteoclastogenesis via suppression of RANKL in osteoblasts (17). As revealed in Fig. 4D, treatment with TM decreased the number of tartrate-resistant acid phosphatase (TRAP)-positive osteoclasts in the bone marrow tumor invasion front. The present findings are consistent with those of Morisawa et al Imunohistochemical analysis of tumor-inoculated mouse tibia bone marrow was performed. Fig. 5A reveals a representative low magnification image of an HSC-3-inoculated mouse tibia bone marrow section stained with H&E and DAPI. The immunohistochemical analysis revealed a marked increase in the number of cleaved caspase-3-positive tumor cells in HSC-3 tumor sections from the cisplatin-treated mice. Whereas TM alone did not increase the expression of cleaved caspase-3, the dual treatment of TM+cisplatin enhanced the expression of cleaved caspase-3 compared to the treatment with either TM or cisplatin alone (Fig. 5B). The expression of the cell growth indicator Ki-67 was also evaluated in low-dose cisplatin-treated mice. Although TM did not affect Ki-67 expression, the TM+cisplatin dual treatment significantly decreased the expression of Ki-67 (Fig. 6A). TM treatment did not affect the expression of IL-6 which is an important...
bone remodeling factor (Fig. S2). Collectively these results indicated that TM enhanced the antitumor effect of cisplatin. Finally, immunohistochemical evaluation was conducted to determine the effect of TM on the in vivo expression of the copper transporter ATP7B. Notably, TM decreased the expression of ATP7B compared with the control group. These data indicated that TM enhanced the antitumor effect of cisplatin via an accumulation of cisplatin in the cancer cells (Fig. 6B).

**TM overcomes cisplatin resistance.** The accumulation of cisplatin is decreased in most of the available cisplatin-resistant cell lines, and an active efflux system for cisplatin exists in some of these cell lines (4-12). The results of the present investigations indicated that TM treatment may overcome cisplatin resistance. Mese et al. established the cisplatin-resistant human skin squamous cell carcinoma cell line A431 (18). This cell line (A431-CDDP-R) was used to evaluate the ability of TM treatment to overcome cisplatin resistance. Notably, the parental A431 cells only slightly expressed ATP7B. In contrast, the A431/CDDP-R cells strongly expressed ATP7B (Fig. 7A). To assess the ability of TM treatment to overcome cisplatin resistance in A431/CDDP-R cells, the cells were pretreated with TM for 24 h. The cells were then treated with cisplatin for 24 h. A western blot analysis revealed that the TM treatment

Figure 6. Immunofluorescence analysis of the tumor in the bone marrow in the mouse model of bone invasion. (A, green: High magnification) KI-67, (B, green: High magnification) ATP7B and DAPI stained with blue (n=6/group). ATP7B, ATPase copper transporting beta.
established that tissues from patients with HNSCC expressed high levels of ATP7B in liver cancer cell lines (14). This mechanism may be due to the copper chelator TM enhanced the function of ATP7B, which was also indicated that high extracellular copper levels suppressed CTR1 expression, thereby preventing excess copper influx (27). It was also noted that high extracellular copper levels suppressed CTR1 expression (27), leading to loss of the copper efflux transporter function (28). Cisplatin is the most frequently used platinum-based alkylating agent for several cancers. Cisplatin binds to DNA and causes intra-strand crosslinking, leading to apoptosis (9). Cisplatin is transported into cancer cells via the copper transporter Ctrl (24). Some clinical studies have indicated that the CTR1 expression in tumors was correlated with the therapeutic efficacy of platinum drugs (25,26). It was also noted that high extracellular copper levels suppressed CTR1 expression, thereby preventing excess copper influx (27). However, the role of ATP7B in cancer cells remains unknown. The present findings are the first to demonstrate that the chelation of copper ions by TM inhibited the ATP7B expression in HSC-3 HNSCC cells. Thus, it was surmised that this effect was due to the maintenance of the copper metabolism of cancer cells. Based on our aforementioned results, it was hypothesized that TM inhibited the cisplatin efflux from cancer cells. Then, the role of ATP7B in cisplatin-resistant cancer cells was evaluated. In vitro experiments demonstrated that TM enhanced the caspase-3 cleavage by cisplatin. These results indicate that the copper efflux transporter was a critical mediator of cisplatin efficacy against cancer cells. The present experiments also revealed that TM did not affect the proliferation of HSC-3 HNSCC cells. We reported previously that TM did not inhibit the growth of fibroblasts, osteocytes, osteoblasts, or T cells, which is consistent with other studies (17,29). We also reported the molecular mechanism of TM in osteoclastogenesis in cancer cells (30). To assess the clinical synergistic effects of copper-lowering agents and platinum agents, TM and low-dose cisplatin were administered in a mouse model of bone-destructive HNSCC, and the results indicated that treatment with either low-dose cisplatin or TM alone partially reduced the tumor growth in bone (Fig. 4A-C). Notably, the combination treatment of cisplatin+TM significantly decreased the tumor growth and bone resorption, Ki-67 expression and cleaved caspase-3 expression compared to the single treatment with either agent (Figs. 5 and 6). This additive effect was due to the suppression of HNSCC cell proliferation via an accumulation of caspatin in HNSCC cells and to osteoclast formation by TM (Fig. 4D).

In a clinical setting, the efficacy of cisplatin-based chemotherapy against cancers is limited by the occurrence of innate and acquired drug resistance, and a recent study revealed that the mechanism of cisplatin resistance is based on the copper transporter regulation in cancer cells (31). In the present study, the administration of cisplatin increased the level of the cisplatin efflux transporter ATP7B. We hypothesized that cancer cells increase the expression of ATP7B to escape from cisplatin accumulation and cell death. To evaluate the mechanism of the function of ATP7B in cisplatin resistance, (epidermoid carcinoma) A431 cells were used. Mese et al established cisplatin-resistant A431 cells (18,19). The expression of ATP7B in parental A431 and cisplatin-resistant A431 (A431 CDDP-R) cells was evaluated, and notably, the ATP7B expression in the A431CDDP-R cells was markedly increased compared to the expression in the parental A431 cells. It was speculated that the cisplatin-resistant A431 cells discharged cisplatin via an increase in ATP7B expression. The present experiments demonstrated that TM enhanced the caspase-3 cleavage by cisplatin. These
results indicated that the mechanism of cisplatin resistance in A431 CDDP-R cells is attributable to an acceleration of the efflux of cisplatin from cells. However, the present data revealed one possibility that ATP7B expression is associated to cisplatin resistance. ATP7B knockdown or a knock-out HNSCC cell line must be established to demonstrate this hypothesis in a future experiment.

In summary, to the best of our knowledge, the present study is the first to reveal that a copper-lowering agent could be an adjuvant to therapy with platinum agents against HNSCC, and the present findings strongly indicate that TM with cisplatin may be an effective approach for treating advanced HNSCC. A clinical study conducted at the MD Anderson Cancer Center revealed that copper-lowering agents have the potential to overcome cisplatin resistance in ovarian cancer patients by regulating the copper transporter hCtrl (32). The present in vitro and in vivo results strongly support the notion that copper-lowering agents including TM could be a clinically effective breakthrough for overcoming cisplatin resistance. A copper-lowering agent could be an adjuvant to therapy with platinum agents against HNSCC, and the present findings strongly suggest that TM with cisplatin may be an effective approach to treat advanced HNSCC.
