Abstract. It is estimated that one-half of patients with non-small cell lung cancer (NSCLC) undergo radiotherapy worldwide. However, the outcome of radiotherapy alone is not always satisfactory. The aim of the present study was to evaluate the effects of radiotherapy on the malignancy of NSCLC cells. It was demonstrated that radiation therapy could increase the migration and invasion of NSCLC cells *in vitro*. Moreover, the upregulation of visfatin, a 52-kDa adipokine, mediated radiation-induced cell motility. A neutralizing antibody specific for visfatin blocked radiation-induced cell migration. Radiation and visfatin induced the expression of Snail, a key molecule that regulates epithelial to mesenchymal transition in NSCLC cells. Furthermore, visfatin positively regulated the mRNA stability of Snail in NSCLC cells, but had no effect on its protein degradation. This may be explained by visfatin-mediated downregulation of microRNA (miR)-34a, which was shown to bind the 3' untranslated region of Snail mRNA to promote its decay. Collectively, these findings suggested that radiation could induce cell motility in NSCLC cells through visfatin/Snail signaling.

Introduction

As the leading cause of cancer mortality, lung cancer accounts for 18.2% of total cancer deaths worldwide (1). Furthermore, ~80% of patients with lung cancer patients have non-small-cell lung cancer (NSCLC). The incidence of NSCLC has increased in women during the last two decades worldwide (2). It has been reported that the 5-year survival rate of NSCLC is <15% (3). Surgical resection, conventional chemotherapy

and radiotherapy are widely used for the clinical treatment of patients with NSCLC (4).

During the course of treatment, one-half of all patients with NSCLC patients undergo radiotherapy (5). It has been reported that early-stage patients can benefit from stereotactic body radiation therapy (6). Stereotactic body radiation therapy has been used as a standard care modality in medically inoperable patients with early-stage NSCLC (7). However, previous studies have indicated that the outcome of radiotherapy alone is not always satisfactory (8), which may be due to the development of radiotherapy resistance (9,10). Moreover, laboratory and clinical data indicated that radiotherapy may cause clinical adverse effects for patients with NSCLC. For example, radiotherapy can increase tumor invasion and metastasis by upregulating TGF β -1 expression (11). Cancer cells treated with radiation acquire mesenchymal-like morphology (12). X-ray irradiation can also increase the invasion of NSCLC cells (13). In addition, radiation can stimulate the malignancy of residual, incompletely treated and viable tumors surrounding the treatment zone (14,15). Thus, understanding the mechanisms involved in radiation-induced malignancy in NSCLC cells is needed in order to improve the therapeutic efficacy of radiotherapy.

Cytokines, such as visfatin, are involved in the progression of NSCLC (16). It has been reported that visfatin mediates doxorubicin (Dox) resistance of human NSCLC cells through Akt-mediated upregulation of ATP-binding cassette subfamily C member 1 (17). Furthermore, visfatin triggers cell motility of NSCLC cells by increasing the expression of matrix metalloproteinases (MMPs) (18). Targeted inhibition of visfatin has been proposed as a potential therapeutic approach for NSCLC treatment (19). Visfatin is a cytokine synthesized and released by adipocytes and inflammatory cells (20). Its expression can also be induced during radiation therapy in cancer tissues (21,22). However, whether visfatin is involved in radiation-induced malignancy of NSCLC remains unknown.

Epithelial-mesenchymal transition (EMT) is the first step of tumor metastasis (23) and is critical to the progression and metastasis of NSCLC (24). During EMT, transcription factors, such as Snail, can bind to the E-box motif of the E-cadherin (E-Cad) gene promoter and inhibit its expression (25,26). In a previous study, high protein expression of Snail is detectable in 21% of NSCLC samples (27). The levels of Snail are associated with poor prognosis in patients with NSCLC (28). It has been reported that the protein expression

Key words: radiation, non-small cell lung cancer, Snail, visfatin, microRNA-34a

of Snail is essential for EMT induction in NSCLC cells (29). In the present study, the expression levels of cytokines, such as IL-6, IL-8, IL-10, VEGFA, TGF- β , TNF- α and visfatin were examined in NSCLC cell lines treated with radiation. Further, the potential roles and mechanisms of visfatin in radiation-induced migration and invasion of NSCLC cells were investigated.

Materials and methods

Cell culture and radiation treatment. The human NSCLC A549 and H1299 cell lines and human bronchial epithelial cells (HBEpC) were purchased from American Type Culture Collection and maintained in DMEM (Invitrogen; Thermo Fisher Scientific, Inc.) supplemented with 10% FBS (Gibco; Thermo Fisher Scientific, Inc.), penicillin and streptomycin at 37°C in 5% CO₂. *Mycoplasma* contamination was monitored weekly during experiments. Radiation treatment was conducted according to a previous study (30). Briefly, 5x10⁵ cells/well were seeded in a 6-well plate and were irradiated at room temperature using a 6 MV X-ray linear accelerator (Varian 23Ex; Varian Inc.) at a dose rate of 300 cGy/min for the time required to apply the dose used in each assay. In order to determine the role of visfatin, anti-visfatin neutralizing antibody (100 ng/ml) or recombinant-visfatin (rVisfatin; 100 ng/ml) were added into culture medium for 24 h at 37°C in 5% CO₂, then irradiated at room temperature.

Reagents. Scramble negative control (NC) microRNA (miR, 5'-UUCUCCGAACGUGUCACGUTT-3'), miR-34a inhibitor (5'-AAGCUCCAUUUCGCAACCUUAC-3'), small interfering RNA (siRNA) NC (si-NC; 5'-GCACAACAAGCCGAUACA-3') and siRNA targeting Snail (5'-CAUCCGAAGCCACACG CUG-3') were purchased from Sigma-Aldrich; Merck KGaA. The neutralizing antibody specific for visfatin (anti-Visfatin; cat. no. A300-778A) and recombinant visfatin (cat. no. RP-75758) were obtained from Invitrogen; Thermo Fisher Scientific, Inc.

Wound healing and Transwell Matrigel™ assay. Cells (1.5x10⁶ cells per well) were plated in 12-well plates and cultured to 80% confluence in complete medium. The cell layer was scratched with a 200 μ l pipette tip, washed twice with PBS, then cultured with medium containing 0.5% FBS, with or without the indicated treatments, as described in Figure legends. The migration distance was recorded in the same visual fields under a phase-contrast microscope. The relative migration rate was calculated according to a previous study (31), using the following formula: [(scratch area at 0 h-scratch area at 48 h)/scratch area at 0 h] x 100%.

Cell invasion was assessed using a Transwell Matrigel invasion chamber (8- μ m pore filters; Corning, Inc.) according to the manufacturer's instructions. A total of 2x10⁵ cells was seeded into the upper chamber of a 24-well chamber with FBS-free medium. The bottom chamber received 0.6 ml complete medium. After the indicated treatment and culture for 24 h, the invading cells were fixed using methanol for 15 min at room temperature, dried under a laminar flow safety cabinet, stained with 0.5% crystal violet (Sigma-Aldrich; Merck KGaA) for 2 h at room temperature, then observed under an inverted optical microscope. The number of invading cells in five randomly

selected fields of view was quantified using ImageJ software version 1.47 (National Institutes of Health). The relative invasion rate was calculated by dividing the number of stained cells by the number of stained cells in the control group.

Reverse transcription-quantitative (RT-q) PCR analysis. Total RNA was isolated using TRIzol® reagent (Invitrogen; Thermo Fisher Scientific, Inc.). cDNA was generated by using the PrimeScript RT reagent kit with gDNA Eraser (Takara Biotechnology Co., Ltd.) for mRNA at 37°C for 15 min, or the qScript microRNA cDNA synthesis kit (Quantabio) for miRNA at 37°C for 60 min followed by 5 min at 70°C, respectively. For mRNA targets, qPCR was conducted using a SYBR-Green PCR Kit (Qiagen GmbH) on the Step-One Plus Real-Time PCR System (Applied Biosystems, Inc.). The thermocycling conditions consisted of an initial denaturation at 95°C for 5 min, followed by 50 cycles at 95°C for 15 sec and 60°C for 30 sec. The primer sequences were as follows: i) IL-6 forward, 5'-CCT CCAGAACAGATTTGAGAGTAGT-3' and reverse, 5'-GGG TCAGGGGTGGTTATTGC-3'; ii) IL-8 forward, 5'-GAGAGT GATTGAGAGTGGACCAC-3' and reverse, 5'-CACAAACCCT CTGCACCCAGTTT-3'; iii) IL-10 forward, 5'-GTGGCATT C AAGGAGTACCTC-3' and reverse, 5'-TGATGGCCTTCGAT TCTGGATT-3'; iv) VEGFA forward, 5'-TACCTCCACCATGCC AAGTGGT-3' and reverse, 5'-AGGACGGCTTGAAGATG TAC-3'; v) TGF- β forward, 5'-GGCCAGATCCTGTCCAAGC-3' and reverse, 5'-GTGGGTTTCCACCATTAGCAC-3'; vi) TNF- α forward, 5'-CCTCTCTCTAATCAGCCCTCTG-3' and reverse, 5'-GAGGACCTGGGAGTAGATGAG-3'; vii) visfatin forward, 5'-AGGGTTACAAGTTGCTGCCACC-3' and reverse, 5'-CTCCACCAGAACCGAAGGCAAT-3'; viii) Snail forward, 5'-GACCACTATGCCGCGCTCTT-3' and reverse, 5'-TCGCTGTAGTTAGGCTTCCGATT-3'; ix) Slug forward, 5'-AGCAGTTGCACTGTGATGCC-3' and reverse, 5'-ACACAGCAGCCAGATTCTCTC-3'; x) Twist forward, 5'-CGG ACAAGCTGAGCAAGATT-3' and reverse, 5'-CCTTCTCT GGAAACAATGAC-3'; xi) Zeb1 forward, 5'-GCACCTGAAGA GGACCAGAG-3' and reverse, 5'-TGCATCTGGTGTTCAT TTT-3'; xii) GAPDH forward, 5'-GTCAACGGATTTGGTCTGT ATT-3' and reverse, 5'-AGTCTTCTGGGTGGCAGTGAT-3'.

For miR targets (miR-137, miR-34a, miR-153 and miR-22), qPCRs were performed using the NCode miRNA qRT-PCR analysis kit (Invitrogen; Thermo Fisher Scientific, Inc.). The thermocycling conditions included an initial denaturation at 95°C for 3 min followed by 40 cycles at 95°C for 15 sec and 60°C for 30 sec. The forward primer is the exact sequence of the mature miRNA. The forward primer for U6 was 5'-TGCGGGTGCTCGCTTCGCAGC-3'. Gene expression levels were calculated using the 2^{- $\Delta\Delta$ Cq} method (32) and standardized to GAPDH and U6 for mRNA and miR targets, respectively. All RT-qPCR reactions were performed three times.

Western blot analysis. Cells were lysed using RIPA buffer (Beyotime Institute of Biotechnology) and protein extracts were collected. Protein concentration was measured using a BCA Protein Assay Kit (Pierce™; Thermo Fisher Scientific, Inc.). After denaturation in boiling water for 10 min, proteins (20 μ g per lane) were separated by SDS-PAGE on 10% gels, then transferred to PVDF membranes. The membranes were blocked with 5% skimmed milk at room temperature for 2 h,

and then incubated with primary antibodies at 4°C for at least 15 h. The primary antibodies used were specific for GAPDH (cat. no. ab9485; Abcam; 1:1,000), E-Cad (cat. no. 14472S; Cell Signaling Technology, Inc.; 1:1,000) and Snail (cat. no. ab82846; Abcam; 1:1,000). Membranes were incubated with HRP-conjugated secondary antibodies (cat. no. ab7090; Abcam; 1:10,000 dilution) for 90 min at 25°C. The protein were visualized using RapidStep™ ECL detection reagent (EMD Millipore) in a GeneGnome XRQ Chemiluminescence Imaging System (Syngene). The gray values were analyzed using the ImageJ software (version 1.46; National Institutes of Health). GAPDH primary antibody was used as a control.

ELISA. The levels of visfatin in culture medium were measured using the Namp1/Visfatin human ELISA kit (cat. no. RAG004R; BioVendor R&D) according to the manufacturer's instructions. The absorbance was measured at 450 nm using a microplate reader (BioTek Instruments, Inc.)

Protein and mRNA stability assay. Protein and mRNA stability was evaluated as previously reported (33,34). Briefly, cells were treated with 10 µg/ml cycloheximide (CHX; Sigma-Aldrich; Merck KGaA) or 5 µg/ml actinomycin-D (Act-D; Sigma-Aldrich; Merck KGaA) for the indicated time periods. mRNA and protein expression levels were measured by RT-qPCR and western blot analysis, respectively.

Dual luciferase reporter assay. Dual luciferase reporter assays were carried out as described previously (35). Briefly, the wild-type (WT) Snail 3'-untranslated region (3'-UTR) luciferase vector containing the putative binding site for miR-34a was purchased from OriGene Technologies, Inc., then mutated using the QuickChange Mutagenesis kit (Stratagene) to produce the mutant (MUT) Snail 3'-UTR construct. Both WT and mutant Snail 3'-UTR were subcloned into the pmiR-GLO plasmid (Promega Corporation). A549 cells in 96-well plate (5x10³ cells/well) were transfected with the pmiR-GLO-WT or pmiR-GLO-Mut, together with scramble control or miR-34a inhibitor for 24 h. The activity was measured immediately at the end of the transfection period. Luciferase activity was analyzed as previously reported (35) using the Dual-Luciferase® Reporter Assay system (Promega Corporation). The Firefly luciferase activity was normalized to Renilla luciferase activity.

Cell transfection. All miRNA mimics, inhibitors, siRNAs and the respective negative control were transfected using Lipofectamine® 2000 (Invitrogen; Thermo Fisher scientific, Inc.) according to the manufacturer's protocol at concentration of 10 nmol/l in transfection medium (αMEM with 10% fetal calf serum, both from Thermo Fisher Scientific, Inc.). Briefly, cells were cultured to 50-60% confluence. The culture medium was then replaced with transfection medium. After incubation with RNA oligonucleotides for 6 h, the transfection medium was replaced with full medium, and the cells were incubated for another 24 or 48 h before harvest.

Statistical analysis. Data are presented as the mean ± SD of three independent experiments and analyzed using SPSS 20 (IBM Corp.). Differences between two experimental groups

were assessed using unpaired Student's t-test (two-tailed). One-way ANOVA followed by Tukey's post hoc test was used when making pairwise comparisons among ≥3 groups. P<0.05 was considered to indicate a statistically significant difference.

Results

Radiation increases the motility of NSCLC cells. In order to evaluate the potential effects of radiation on the characteristics of NSCLC cells, A549 and H1299 were treated cells with 5 Gy of radiation according to previous studies (30,36-38). This radiation dose significantly increased the *in vitro* migration rate of both A549 (Fig. 1A) and H1299 (Fig. 1B) cells. A Transwell invasion assay confirmed that 5 Gy of radiation could increase the *in vitro* invasion of both A549 and H1299 cells (Fig. 1C). Moreover, the expression of E-Cad in cells was measured following incubation with 1-10 Gy of radiation. Radiation decreased the mRNA expression levels of E-Cad in both A549 and H1299 cells in a dose-dependent manner (Fig. 1D). Western blot analysis confirmed that radiation reduced E-Cad protein expression in A549 and H1299 cells (Fig. 1E). These findings suggested that radiation increased the motility of NSCLC cells.

Radiation increases the expression of visfatin in NSCLC cells. It has been suggested that cytokine levels are critical for the metastasis of NSCLC cells and might be modulated by radiation (16,39). The expression levels of IL-6, IL-8, IL-10, VEGFA, TGF-β, TNF-α and visfatin were therefore measured, since these cytokines have been shown to be critical for the motility and metastasis of NSCLC cells (40,41). Radiation significantly increased the expression of visfatin in both A549 (Fig. 2A) and H1299 (Fig. 2B) cells. Radiation-induced expression of visfatin was also confirmed in both cell lines using ELISA (Fig. 2C). Furthermore, RT-qPCR demonstrated that radiation increased mRNA expression of visfatin in A549 cells in a dose-dependent manner (Fig. 2D). RT-qPCR (Fig. 2E) and ELISA (Fig. 2F) also indicated that visfatin expression was significantly increased in A549 and H1299 cells, compared with HBEPcs.

Visfatin is essential for radiation induced cell motility. Previous studies have indicated that visfatin is critical for NSCLC development and malignancy (18,42). Thus, to determine whether visfatin was involved in radiation-regulated cell motility, cells were treated with a visfatin neutralizing antibody. Wound healing assays indicated that visfatin blockade inhibited migration in A549 cells, both under control conditions and following irradiation (Fig. 3A). Similarly, a Transwell invasion assay also confirmed that the anti-visfatin antibody inhibited radiation-induced invasion of A549 cells (Fig. 3B). Furthermore, visfatin blockade reversed the radiation-induced downregulation of E-Cad, both in A549 (Fig. 3C) and in H1299 (Fig. 3D) cells.

Snail is involved in radiation- and visfatin-induced cell migration. Since E-Cad was significantly decreased during radiation-induced cell migration, it was hypothesized that EMT-TF such as Snail, Slug, Twist, and Zeb1 might be involved in this process. Radiation significantly increased the mRNA expression

levels of Snail in both A549 (Fig. 4A) and H1299 (Fig. 4B) cells. Further, western blot analysis confirmed that radiation increased the protein expression levels of Snail in both cell lines (Fig. 4C). However, radiation-induced expression of Snail could be blocked following treatment with the anti-visfatin neutralizing antibody in both A549 (Fig. 4D) and H1299 (Fig. 4E) cells. In addition, Snail siRNA knockdown reversed the radiation-induced down-regulation of E-Cad (Fig. 4F).

Visfatin regulates the mRNA stability of Snail. The mechanisms involved in visfatin-mediated regulation of Snail expression were further examined. The anti-visfatin neutralizing antibody decreased the mRNA levels of Snail in both A549 and H1299 cells (Fig. 5A). Conversely, rVisfatin increased Snail mRNA levels in both cell lines (Fig. 5B). Additionally, the mRNA and protein stability of Snail was evaluated in NSCLC cells. The results suggested that anti-visfatin could decrease stability of Snail at the mRNA level in both A549 (Fig. 5C) and H1299 (Fig. 5D) cells following Act-D treatment. However, anti-visfatin had no effect on the stability of Snail protein in A549 cells (Fig. 5E) following CHX treatment.

Visfatin may regulate Snail expression through miR-34a. miRNA molecules can decrease mRNA stability by binding to its 3'-UTR (43). It has been suggested that miR-137 (35), miR-34a (35), miR-153 (44), and miR-22 (45) can directly target Snail mRNA to inhibit its expression and reduce its stability. In the present study, anti-visfatin significantly increased the expression of miR-34a in both A549 (Fig. 6A) and H1299 (Fig. 6B) cells. Similarly, radiation also reduced the expression of miR-34a in both cell lines (Fig. 6C). Moreover, transfection with the miR-34a inhibitor significantly increased the luciferase activities of reporter vector containing the WT Snail 3'-UTR. However, this effect was abrogated following transfection with the MUT Snail 3'-UTR, which contained mutations targeting the predicted binding site of miR-34a (Fig. 6D). These results demonstrated the direct binding between miR-34a and the 3'-UTR of Snail. Furthermore, treatment with the anti-visfatin neutralizing antibody reduced the luciferase activity of the reporter vector containing the Snail 3'-UTR, whereas the addition of miR-34a inhibitor abolished this effect (Fig. 6E). The miR-34a inhibitor was then used to evaluate whether miR-34a was involved in visfatin-mediated

regulation of Snail expression (Fig. 6F). The results showed that the miR-34a inhibitor could reverse the downregulation of Snail mRNA (Fig. 6G) and protein (Fig. 6H) induced by visfatin blockade in A549 cells. In addition, the miR-34a inhibitor promoted migration and reversed the effect of the anti-visfatin antibody on the migration of A549 cells (Fig. 6I).

Discussion

Although radiotherapy is widely used for NSCLC treatment, the efficacy of this therapeutic approach is not always satisfactory, even in the absence of radioresistance (8). Previous studies have indicated that residual cancer cells cancer survive following radiotherapy in many cancer types and become more malignant (46,47). For instance, radiation can increase the metastatic ability of cancer cells through the induction of EMT (48,49). In the present study, radiation was found to

induce the migration and invasion of NSLC cells, as evidenced by the results of wound healing assays and invasion assays, as well as E-Cad downregulation. Similarly, previous studies have demonstrated that radiation could upregulate MMP-2 and MMP-9 in NSCLC cells, resulting in increased invasion and migration of lung cancer cells (13,50). γ -ionizing radiation (IR) also induces migration/invasion of NSCLC cells (51). Thus, consistent with previous reports, our present findings highlighted the potential adverse effects of radiotherapy on NSCLC progression.

In the present study, visfatin was essential for radiation-induced motility of NSCLC cells. Visfatin has been reported to regulate angiogenesis, inflammation, and cell viability (52). A study has indicated that expression of visfatin is increased in cancer tissues as compared to that in the normal tissues (53). Furthermore, visfatin promotes the invasion and migration of several cancer types, such as

hepatocellular carcinoma (54) and colorectal carcinoma (55). It is also involved in resistance to Dox treatment in colorectal cancer (56). Visfatin is upregulated in lung cancer cells and tissues (42); it also regulates the EMT and invasion of NSCLC cells (18), as well as Dox sensitivity (17). In the present study, visfatin was upregulated after radiation therapy, and visfatin blockade with a neutralizing attenuated radiation-induced cell motility. This suggested that visfatin could promote the malignancy of lung cancer.

The present study revealed that miR-34a/Snail is involved in visfatin-regulated radiotherapy-induced malignancy of NSCLC cells. Moreover, it has been reported that visfatin can upregulate the expression of Snail to induce EMT-like properties in osteosarcoma cells (57) and colorectal cancer (55). In NSCLC cells, visfatin upregulates Snail expression by increasing its mRNA stability, likely by decreasing the expression of miR-34a. Previous studies have indicated that Snail was the direct target of miR-34a in gastric (58), pancreatic (59), and ovarian (35) cancer cells. In addition, Snail directly induces ZNF281 transcription and represses miR-34a/b/c, thereby alleviating ZNF281 mRNA from direct down-regulation by miR-34 and promoting the EMT of lung cancer cells (60). However, the mechanisms underlying visfatin-regulated expression of miR-34a remain unclear.

In summary, the present study demonstrated that radiation increased the malignancy of NSCLC cells through visfatin upregulation. miR-34a-regulated mRNA stability of Snail and was involved in radiation/visfatin regulated motility of NSCLC cells. Although the detailed mechanisms underlying the role of visfatin and miR-34a remain to be determined, these findings highlighted the adverse effects of radiotherapy on NSCLC cell motility.

The datasets used and/or analyzed during the current study are available from the corresponding author on reasonable request.

Authors' contributions

LX, YM, ZT, YZ, HH and FW conceived and designed the study. LX, YM and FW acquired the data. LX, YM and HH analyzed and interpreted the data. LX, HH and FW wrote, reviewed and revised the manuscript. All authors read and approved the final manuscript. LX and FW confirm the authenticity of the raw data. All authors read and approved the final manuscript.

Ethics approval and consent to participate

Not applicable.

Patient consent for publication

Not applicable.

Competing interests

The authors declare that they have no competing interests.
