Abstract. (-)-Epigallocatechin-3-gallate (EGCG) has inhibitory effect on a variety of cancers by inducing apoptosis and cell cycle arrest or inhibiting angiogenesis and metastasis. EGCG has been found to induce apoptosis in salivary gland carcinoma cells, however, it is not known whether EGCG affects invasion and migration. Thus, this study was performed to clarify whether EGCG affects invasion and migration of salivary gland tumors. Matrigel invasion assay, wound scratch assay and migration assay using commercial kit were performed. B1 integrin expression and activation of its downstream molecules such as focal adhesion kinase (FAK), AKT and extracellular signal-regulated kinase (ERK) were examined by Western blot. Enzymatic activity of matrix metalloprotease (MMP)-2 and MMP-9 was examined by gelatin zymography. EGCG inhibited effectively invasion and migration of SGT cells in a dose-dependent manner. EGCG also inhibited the activation of B1 integrin-downstream molecules such as FAK, AKT and ERK as well as the expression of B1 integrin itself. Moreover, MMP-2 and MMP-9 expression and their enzymatic activity were reduced by EGCG in a dose-dependent manner. These results indicate that EGCG may effectively suppress salivary gland tumors by inhibiting metastasis through B1 integrin-mediated signaling.

Introduction

Salivary gland cancers account for <0.5% of all malignancies and approximately 3-6% of all head and neck tumors in adults (1-3). Little is known about the etiology of salivary gland cancers. Radiation exposure and a history of any prior cancer are the established risk factors for salivary gland tumors (4-6). Epstein-Barr virus can be a factor for the development of lymphoepithelial salivary gland tumors (7). The WHO classification of malignant salivary gland tumors has been recently updated, listing 24 different histologic subtypes (8). The main four histopathologic types include mucoepidermoid carcinoma (29-34% of malignant tumors), adenoid cystic carcinoma (about 20%), adenocarcinoma and salivary duct carcinoma.

Salivary gland carcinomas are primarily managed with surgical resection, often in conjunction with postoperative radiation therapy (9). The functions of chemotherapy in the management of salivary gland cancers remain unsolved (2). Chemotherapy is generally indicated only for palliation in symptomatic patients with recurrent and/or unresectable cancers (9), because response rates of salivary gland cancers to chemotherapy are inconsistent, varied and generally poor (10).

Green tea is one of the most popular beverages in the world because it has many beneficial effects on human health. It contains many catechins such as (-)-epigallocatechin-3-gallate (EGCG), (-)-epigallocatechin (EGC), (-)-epicatechin-3-gallate (ECG) and (+)-catechin (11). EGCG is the most abundant polyphenol in green tea and has been found to inhibit growth of tumor cells by inducing apoptosis or inhibiting angiogenesis (12,13). In addition, EGCG inhibits invasion and metastasis of a variety of tumor cells (14-17). Sakagami's group showed that EGCG induced apoptosis of human salivary gland tumor HSG (18,19). However, there is no report about the effect of EGCG on invasion and migration of salivary gland adenocarcinoma SGT cells. Therefore, in this study, we examined the effect of EGCG on adhesion, invasion and migration of salivary gland adenocarcinoma SGT cells.

Materials and methods

Cell culture. SGT human salivary gland adenocarcinoma cells (a gift from Professor C.H. Lee, Dankook University) (20) were cultured in Dulbecco's modified Eagle's medium (DMEM) supplemented with 10% fetal bovine serum, 100 μg/ml streptomycin and 100 units/ml penicillin at 37°C in a 5% CO2 incubator.

MTT assay. To determine a concentration to be used in the further experiment, cell viability was examined using the MTT assay. The cells were seeded at 3x10^4 cells/ml into the 12-well plates and treated with different concentrations of
EGCG (Cayman Chemical Co., Ann Arbor, MI) for 24 h. Cells were washed twice with ice-cold PBS, and 0.5 ml of cell culture medium and 50 μl of 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide reagent (5 mg/ml in PBS) were added and incubated for 3 h at 37°C. The media were then removed and 250 μl of acid-isopropanol (0.04 mol/l HCl in isopropanol) was added. The optical density (OD) was then measured by a Microplate Autoreader ELISA (Bio-Tek Instruments, Inc., Winooski, VT) at 570 nm wavelength.

**Matrigel invasion assay.** Cell invasion assay was performed using a Matrigel invasion assay kit (BD Biosciences, San Jose, CA) according to the manufacturer's instructions. Briefly, serum-free media supplemented with EGCG was added to the well. Cells were seeded in the insert of the transwell plate and incubated for 22 h at 37°C. The cells that invaded to the lower surface of the membrane were fixed with methanol and stained with hematoxylin for 5 min. On microscopy, five areas from each sample were randomly selected and invasion cells were counted as previously described (21).

**Wound-scratch assay.** The cells were allowed to grow in culture dish overnight and a scratch about 3 mm in width was made of in monolayer by yellow tip. After washing twice with PBS, the cells were cultured in the absence or presence of EGCG, and photographs were taken in series at different time-points.

**Cell migration assay.** Cell migration assay was performed using a Chemotaxis Cell Migration Assay kit (Chemicon) according to the manufacturer's instructions. Briefly, EGCG was treated in culture media outside of the insert. The cells were added to the insert and incubated for 24 h. The migrated cells to the lower surface of the membrane were processed and counted as described in invasion assay. To quantify migration ability, migrated cells are lysed using the cell lysis buffer and optical density was measured with the CyQUANT GR Dye using fluorescence plate reader (Varioskan, Thermo Electron Co., Waltham, MA) at 480/520 nm.

**Western blot analysis.** After treated with EGCG, the cells were lysed in lysis buffer (137 mM NaCl, 15 mM EGTA, 0.1 mM sodium orthovanadate, 15 mM MgCl2, 0.1% Triton X-100, 25 mM MOPS, 100 μM phenylmethylsulfonyl fluoride and 20 μM leupeptin, adjusted to pH 7.2). The total protein (40-50 μg per lane) was resolved by 7.5-15% SDS-PAGE and transferred onto PVDF membranes. After blocking in TBS (20 mmol/l Tris, 137 mmol/l NaCl, 1 g/l, pH 7.6) with 5% skim milk for 2 h at room temperature, the membranes were incubated with primary antibodies at 37°C overnight. Antibodies of β1 integrin, focal adhesion kinase (FAK), pFAK, matrix metalloprotease (MMP)-2, and MMP-9 were from Santa Cruz Biotechnonology (Santa Cruz, CA). In addition, antibodies of Akt, pAkt, extracellular signal-regulated kinase (Erk) and pErk were from Cell Signaling (Danvers, MA). The membranes were then washed three times with a 0.05% tween-TBS (TBS-T), followed by incubation for 1 h with secondary antibodies (1:5000; Santa Cruz Biotechnology) at room temperature. Finally, the membranes were visualized using the West ZOL Plus detection reagent in the LAS-1000 (Fujifilm, Japan).

**RT-PCR.** The primer sets used in this study were as follows. β1 integrin, F: 5'-ATGCCCTACTTCTGCACGATGTG-3', R: 5'-GATGGCATCGAAGCACTC-3'; MMP-2, F: 5'-CTCCATTGAGGCTGATG-3', R: 5'-TCTCCCAAGGTCATAUGCCTCA-3'; MMP-9, F: 5'-CTCTCAAGGTTAATCTGCAACCT-3'; GAPDH, F: 5'-GATGGCATCGAAGCACTC-3', R: 5'-GTCATACCGAATGAGCTTGACA-3'. cDNA synthesis and reverse-transcription polymerase chain reaction (RT-PCR) were performed from 2 μg total RNA using an One Step RT-PCR kit (iNtRON Biotechnology, Seongnam, Korea). The PCR condition consisted of an initial denaturation at 94°C for 2 min; 30 cycles of 94°C for 15 sec, 55°C for 30 sec and 72°C for 1 min; a final extension at 72°C for 10 min. The PCR products were separated on a 1.2% agarose gel, visualized and photographed using a gel documentation system.

**Gelatin zymography.** MMP-2 and MMP-9 enzymatic activities were assayed by gelatin zymography. Supernatants from EGCG-treated cultures were electrophoresed on an 8% SDS-PAGE containing gelatin. The gel was washed three times with renaturing buffer, followed by a brief rinsing in distilled water, and then incubated with development buffer at 37°C. After incubation, the gel was stained with Coomassie Brilliant Blue G250 (0.1% in 25% methanol and 10% acetic acid in water) and destained in the same solution in absence of the dye (22).

**Statistical analysis.** The differences in mean values among different groups were tested, and the values were expressed as mean ± SD. All of the statistical calculations were carried out using Microsoft Excel. Values of P<0.05 were considered significant.

**Results**

**Effect of EGCG on the viability of SGT cells.** To determine a concentration to be used in the further experiments, the cell viability was examined by MTT assay at the absence or presence of EGCG. Cell viability was slightly decreased by EGCG in a manner dependent on dose, but which is not significant (Fig. 1). Even at the highest concentration (200 μM),...
EGCG induced only about 10% decrease of viability of SGT cells. Therefore, we determined to use 100 and 200 μM EGCG in further experiments.

Effect of EGCG on invasion and migration of SGT cells. Cell invasion and migration are of fundamental importance in tumor metastasis and angiogenesis (23,24). Therefore, we examined the effect of EGCG on invasion and migration of SGT cells. Treatment of EGCG significantly reduced the number of invading cells in a dose-dependent manner (Fig. 2). Cell migration was evaluated by two systems including wound-scratch assay and cell migration assay using a commercial kit. The migration of SGT cells across the wounded space was inhibited by EGCG in a time- and dose-dependent manner (Fig. 2). Moreover, the number of cells passing through membrane was dose-dependently decreased by EGCG (Fig. 2A and B). These findings suggest that EGCG suppressed effectively invasion and migration of SGT cells.

Effect of EGCG on the expression of down regulators of β1 integrin. Cell adhesion to extracellular matrix (ECM) is mediated by integrins that play a significant role in tumor progression and metastasis (25). Therefore, we examined the effect of EGCG on the expression of β1 integrin and its downstream molecules. The expression of cell surface β1 integrin

Figure 2. Matrigel invasion assay was performed to examine the effect of EGCG on the invasiveness of SGT cells. The cells were cultured at the absence or presence of EGCG (100 and 200 μM) for 24 h. The cells that invaded to the lower surface of the membrane were fixed and stained with hematoxylin and photographs were obtained from each sample (A). On microscopy, five areas from each sample were randomly selected and invasion cells were counted (B). Results are expressed as mean ± SD. *P<0.05, **P<0.001.

Figure 3. After the cells were fully grown, wound scratch about 3 mm in width was made in the cell culture dish. The cells were then incubated at the absence or presence of EGCG and photographs were taken from each sample at various time-points (A). The length between each wound edge was measured and the wound closure was expressed as percentage compared with the length of first made wound edge (B). As another experiment to examine the effect of EGCG on the migration of SGT cells, cell migration assay was performed. The migrated cells to the lower surface of the membrane were processed and stained. Photograph was taken from each sample (C) and migrating cells were counted as described in invasion assay (D). To quantify migration ability, migrated cells are lysed using the cell lysis buffer and optical density was measured at 480/520 nm (E). Results are expressed as mean ± SD. *P<0.05, **P<0.01, ***P<0.001.
was decreased by EGCG (Fig. 4A). Phosphorylation of FAK, Akt, and Erk was also reduced by EGCG in a dose-dependent manner (Fig. 4A). Moreover, EGCG also inhibited the expression of MMP-2 and MMP-9 in a dose-dependent manner (Fig. 4A). To examine whether EGCG affects the steady-state levels of β1 integrin, MMP-2 and MMP-9 mRNAs, RT-PCR was performed. The level of mRNA expressions for β1 integrin, MMP-2 and MMP-9 was also reduced by EGCG in a dose-dependent manner (Fig. 4B).

**Effect of EGCG on activities of MMP-2/-9.** Extracellular matrix breakdown is pivotal for cellular invasion, indicating that matrix-degrading proteinases are essential for tumor cell metastasis (26). Therefore, we determined the activity of MMP-2 and MMP-9 by gelatin zymography after 24 h incubation with EGCG in SGT cells. As shown in Fig. 5, treatment of EGCG suppressed the gelatinolytic activities of MMP-2 and MMP-9 of SGT cells in a dose-dependent manner.

**Discussion**

Many scientists are interested in natural products because of their various beneficial effects on human health such as anti-inflammation and anti-cancer properties. EGCG, the most abundant catechin in green tea, has been widely studied regarding its beneficial effects on health including anti-cancer effect. EGCG exhibits anti-cancer effect by inducing apoptosis and cell cycle arrest or inhibiting angiogenesis and metastasis (27). It also inhibits the signal transduction pathway related to tumorigenesis such as mitogen-activated protein kinase (MAPK), the activator protein 1 (AP-1), nuclear factorκB (NF-κB), epidermal growth factor receptor (EGFR) or insulin-like growth factor-1 (IGF-1) mediated pathway (27).

Although previous studies revealed that EGCG induced apoptosis of salivary gland carcinoma cells (HSG), its anti-invasion and anti-migration effects on salivary gland malignancies were not reported. In the present study, we showed that EGCG exhibits anti-invasion and anti-migration effect on SGT cells at the concentrations showing little cytotoxicity. EGCG has been reported to inhibit invasion and metastasis of a variety of cancer cells (14-17). Moreover,
EGCG inhibited adhesion and migration of stromal cells such as fibroblasts (28). These findings indicate that EGCG may generally affect adhesion, invasion and migration in a variety of cell types.

The major mechanisms of cancer invasion and migration are that primary cancer cells disseminate and grow at a distant site resulting in a secondary tumor (29). When cancer cells invade and migrate, various proteolytic enzymes contribute to the degradation of extracellular matrix (ECM) (22,30). Integrin receptors play critical roles in cell-to-cell contacts, cell adhesion and migration, and major receptor for cell adhesion and ECM (31). Among the integrins, β1 integrin is known to mediate cell adhesion and migration (32-34). Focal adhesion kinase (FAK) has been shown to regulate integrin-mediated signaling (31,35). After ligand stimulation or integrin engagement, FAK becomes phosphorylated, which leads to the phosphorylation of down regulators such as Akt and Erk. Subsequently, activation of these signaling molecules leads to increase of matrix metalloproteinase (MMP) production, promoting invasion of migration of tumor cells (36-40). Among the MMPs, MMP-2 (gelatinase-A) and MMP-9 (gelatinase-B) are overexpressed in various malignant tumors and play critical roles in tumor invasion and migration (41-43).

In the present study, we examined whether EGCG exhibits its anti-invasion and anti-migration activity in SGT cells through β1 integrin-mediated pathway. EGCG treatment inhibited the activation of its down-stream molecules such as FAK, AKT, and ERK as well as β1 integrin itself. Moreover, MMP-2 and MMP-9 expression was also reduced by EGCG in a dose-dependent manner. EGCG has been also shown to inhibit the enzymatic activity of secreted MMP-2 and MMP-9 in human fibrosarcoma (44). Similarly, our result showed that EGCG treatment led to inhibition of enzymatic activity of MMP-2 and MMP-9 in SGT cells.

In conclusion, invasion and migration are dependent on production of MMP-2 and MMP-9 and their enzymatic activity through β1 integrin-mediated pathway. EGCG inhibited effectively the invasion and migration of SGT cells, β1 integrin expression, activation of FAK, AKT, and ERK, and the MMP-2 and MMP-9 expression and their enzymatic activity of MMP-2 and MMP-9. Our results suggest that EGCG may exhibit beneficial effects on salivary gland tumor progression by inhibiting invasion and migration via β1 integrin-mediated signaling pathway.
