Abstract. Mesenchymal stem cells (MSCs) are excellent sources for use in the treatment of refractory and relapsing disorders mainly due to their hematopoietic-supporting and immunoregulatory capacities. However, their safety and effectiveness for the treatment of refractory atopic dermatitis (AD) and multiple complications in elder patients are largely unknown. Therewith, the present study describes the case of a 65-year-old female patient with AD accompanied by foot ulcers and refractory urinary tract infection. Briefly, 5×10^7 human umbilical cord-derived MSCs (hUC-MSCs) were intravenously infused into the body of the patient after obtaining the approval of the relevant ethics committee and the consent of the patient. The clinical and biochemical outcomes, including general symptoms, hemogram and blood constituents, medical images, together with tumour biomarkers, were observed and recorded. By conducting only one single intravenous infusion of hUC-MSCs, the AD-associated pathophysiological manifestations of the elderly patient, including an unbearable itch,

diffuse erythema and eczema, and in particular, inflammatory foot ulcers and refractory urinary infection were completely attenuated. Simultaneously, the outcomes of the accompanied complications were effectively improved, whereas no recrudescence or adverse reactions were observed in the 14-month follow-up visit. The findings of the present study suggested that the administration of hUC-MSCs was safe and effective for restricting the symptoms and of the patient preventing associated complications. Thus, the use of hUC-MSCs may prove to be a promising treatment option for AD and foot ulcer management, even for elderly patients with multiple underlying conditions or complications.

Introduction

Atopic dermatitis (AD), a heterogeneous skin lesion with an increasing prevalence worldwide, is recognized as the most common chronic and relapsing inflammatory disorder among infants, children and even adults of all races, particularly among families with a history of related allergic diseases (1,2). Overall, AD can be divided into the intrinsic and extrinsic subtypes, which approximately comprises up to 20 and 80% of patients, respectively (3). The disease has been reported to have a complex causality due to a series of immunological, genetic and environmental elements, with resultant comorbidities, such as respiratory diseases, food allergies, inflammatory skin infections and relative autoimmune disorders (1,4). As previously reported by Kim *et al*, the curative efficacy of the current clinical regimens against AD is relatively insufficient, along with marked ambiguity and side-effects (5). Moreover, complications, including xerosis, pruritus and eczematous skin ulcers, further complicate the exploration of the pathogenesis and management of AD (4,6). Thus, considering the increasing evidence that AD has caused a tremendous burden upon patients and their caregivers, there is an urgent need for the establishment of a more systemic therapeutic strategy with which to eliminate the complex pathophysiology together with the accompanied non-allergic and allergic comorbidities (2,7).

Abbreviations: hUC-MSCs, human umbilical cord-derived mesenchymal stem cells; AD, atopic dermatitis; hUCB-MSCs, human umbilical cord blood-derived MSCs; CEA, carcino-embryonic antigen; AFP, alpha fetoprotein; CA, carbohydrate antigen; NSE, neuron-specific enolase; SCCA, squamous cell carcinoma antigen

Key words: human umbilical cord-derived mesenchymal stem cells, atopic dermatitis, foot ulcers, urinary tract infection

Mesenchymal stem cells (MSCs) are immunomodulating cell populations with static adherence and a typically fusiform morphology, with a high-level expression of mesenchymal-associated surface markers, and a multi-lineage differentiation capacity towards adipocytes, osteoblasts and chondroblasts (8). For decades, numerous fundamental research and clinical applications have collectively demonstrated the vast prospects of the use of MSCs in regenerative medicine and the coordinate contributions to the physiological and pathological microenvironment (8-10). For instance, researchers have extensively investigated the cultivate prospects of MSCs in a variety of refractory and relapsing diseases, such as the sports-related injuries (e.g., meniscal injuries) and osteoarthritis (11,12), nervous system disorders (e.g., Alzheimer's disease and spinal cord injuries) (13,14), digestive disorders (e.g., acute-on-chronic liver failure and fulminant hepatic disease) (15,16), endocrine disorders (e.g., diabetes mellitus and related complications) (17,18), reproductive disorders (e.g., premature ovarian failure and intrauterine adhesions) (19,20), haematological disorders (e.g., aplastic anaemia and acute myelogenous leukaemia) (21,22), and in particular, immunodysregulation (graft-vs.-host disease and Crohn's disease) (23,24). Kim *et al* reported that the first-in-class clinical trial upon AD administration with human umbilical cord blood-derived MSCs (hUCB-MSCs), even though hUCB-MSC infusion was well tolerated without noteworthy adverse events; yet, the efficiency together with the crucial effects did not yield statistical significance (5). Above all, the detailed effects of MSCs upon AD-associated skin ulcers and vital signs of elderly patient >60 years of age remain unexplored.

The present study describes the case of a 65-year-old female patient with typical symptoms of severe AD, including unbearable pruritus, xeroderma and systemic eczema plaques with refractory foot skin ulcer. With the aid of hormone and other drug treatments, the pruritus of the elderly patient was transiently attenuated, but relapsed quickly, whereas the other complications did not exhibit a visible improvement. Thus, with the consent of the patient and approval by the relevant ethics committee, 5×10^7 human umbilical cord-derived MSCs (hUC-MSCs) were administered into the body of the patient via intravenous infusion. Notably, the aforementioned symptoms of AD and multiple complications of the patient were completely eliminated without visible side-effects upon examination of systematic vital signs, and in particular, the severe foot ulcers in both feet had subsided. Taken together, the findings of the present study confirm the safety and efficacy of the proof-of-concept use of hUC-MSCs for the treatment of AD. In addition, the present study highlights the prospects of the use of hUC-MSCs for elderly patients with refractory AD-associated severe skin ulcers.

Case report

General description of the patient. In March, 2019, the 65-year-old female patient in question was diagnosed with influenza and a cough, when then subsided, apart from the occasional itch and sporadic eczema spots on the left foot. The patient was treated by an oral administration of a routine dose of levofloxacin according to the drug instructions as suggested by the doctors at the General Outpatient Department,

People's Hospital of Shangrao Economic and Technological Development Zone, Jiangxi Health-Biotech Medical Development Co., Ltd. However, in the middle of April, the area of the original eczema began to gradually increase from 1.0x1.5 to 2.5x5.5 cm, and the local skin turned purple and was accompanied by a persistent itch. After 1 month, a clinical examination revealed a urinary tract infection in the patient. However, a significant remission in symptoms was observed following the administration of norfloxacin (for eczema) for 3 days. Even though the urinary tract infection was temporarily eliminated with the aid of levofloxacin treatment, yet a secondary infection was detected and this became more frequent and severe by mid-July. For the purpose of alleviating the refractory infection and the accompanied erythema in the body, an oral cefixime-based remedy was conducted for 2 weeks. Unexpectedly, the erythema in the double lower limbs diffused and increased gradually, and spread upward from the crus without signs of subsiding at all (Fig. 1A). In addition, ulcerations began to form on the feet and these expanded into the epidermis and dermis (Fig. 1B).

hUC-MSC infusion and safety outcomes. On the basis of the aforementioned information, the clinical expert panel consist of the doctors at the General Outpatient Department, People's Hospital of Shangrao Economic and Technological Development Zone, Jiangxi Health-Biotech Medical Development Co., Ltd. reached the following consensus: The elderly patient was diagnosed with refractory AD accompanied by pruritus, diffuse erythema in the body, severe skin ulcers on the feet and the incorporated urinary tract infection (Fig. 1A and B, and Table SI). Having considered the inefficacious and even cumulative outcomes of the traditionally comprehensive treatment, the patient then received an intravenous administration of 5×10^7 clinical grade hUC-MSCs (Jiangxi Research Centre of Stem Cell Engineering, Jiangxi Health-Biotech Stem Cell Technology Co. Ltd.; product lot no. 201909JF03) via a sterile blood transfusion needle at a rate of 45 drops per min on September 15th, 2020 in 100 ml 0.9% saline after obtaining the ethical approval of the Ethics Committee of People's Hospital of Shangrao Economic and Technological Development Zone, Jiangxi Health-Biotech Medical Development Co., Ltd. and the informed consent of the patient. During the transfusion process, no acute adverse effects or drug-related events, such as infusion-related or allergic reactions (e.g., polypnea, slight trembling, or instantaneous low fever) were observed in the patient with AD. Subsequently, no delayed hypersensitivity, secondary infection, or life-threatening events were observed within the 14-month period of observation as well.

Complete remission of the patient with AD administered the hUC-MSCs. To assess the therapeutic effects of the hUC-MSC administration, the clinical symptoms of the patient with AD were initially evaluated. Generally, the size and crimson colour of the diffuse erythema were collectively and gradually alleviated within the first 10 days and eventually disappeared after 1 month, which indicated the effectiveness of the infusion of MSCs upon AD-associated eczema. Moreover, the unbearable itch and refractory urinary tract infection were also alleviated from the patient with AD. Notably, during the

Figure 1. The pathophysiological examination of the patient with AD. (A) Pathophysiological morphology of eczema plaque in the lower limbs before (left panel) and after (right panel) the hUC-MSC administration. (B) Pathophysiological morphology of refractory ulcers in the left foot before (left panel) and after (right panel) the hUC-MSC administration. AD, atopic dermatitis; hUC-MSC, human umbilical cord-derived mesenchymal stem cells.

14-month follow-up visits, no recrudescence AD-associated pathophysiological events, including itch and erythema, and in particular ulcers on the foot, were observed in the body of the elderly patient (Fig. 1A). Additionally, with only a single hUC-MSC administration, the patient with AD was satisfied with the treatment effects (with the smooth skin) and felt well in body and mind as well, which collectively revealed the improvement of the quality of life (Fig. 1B).

Apart from the subjective and objective changes in the general physical examination of the patient, multifaceted assessments, including vital signs, and detailed clinical and laboratory examinations were collectively conducted upon the patient with AD. Firstly, from the routine urine test and the microscopic examination of leucocytes (R-WBC), a marked decline in the numbers of leucocytes was observed, and a decrease was also observed the content of nitrite in the urine (Tables SI and SII). Secondly, according to blood cell test results of the patient, both blood cell components (e.g., neutrophils, lymphocytes and granulocytes) and biochemical indexes (e.g., bilirubin, alanine aminotransferase, cholesterol and high-density lipoprotein cholesterol) were within the normal ranges, without anomalous changes before treatment and after complete recovery, while the contents of total cholesterol and low-density lipoprotein cholesterol were slightly increased (Tables SI and SII). In addition, following MSC treatment, the dysregulated other blood parameters, such as Casson viscosity, whole blood shear rate 50 and 100, and erythrocyte sedimentation rate were also ameliorated (Tables SI and SII). Above all, as shown by the test results, none of the well-known cancer-associated

parameters with abnormal elevations were observed in the patient with AD, including carcinoembryonic antigen (CEA), alpha fetoprotein (AFP), carbohydrate antigens (e.g., CA-125, CA-133, CA-199, CA-242 and CA-724), neuron-specific enolase (NSE), cytokeratin 19 (CK-19) and squamous cell carcinoma antigen (SCCA) (Tables SI and SII).

Discussion

State-of-the-art renewal has enlightened the promising prospects of MSCs in the management of refractory and relapsing disorders. This is mainly attribute to their unique hematopoietic-supporting and immunoregulatory properties (21,25,26). However, their potential application in elderly patients with refractory allergic dermatitis with multiple complications are largely unknown. The present study describes the case of a 65-year-old female patient with AD accompanied by an unbearable itch, extensive eczema, severe foot ulcers, urinary tract infection, and in particular, resistance to conventional drug therapy. With the aid of only one single systemic hUC-MSC injection, the major symptoms of AD were effectively relieved within 10 days following the MSC administration. Finally, a positive outcome without palindromia was observed with the patient during the 14-month follow-up visit, including the significant elimination of pathophysiological manifestations and persistent improvement in the quality of life.

The pathogenesis of AD typically manifests in epidermal barrier disruption, dysbiosis of the skin microbiota and the overactivation of the helper T lymphocyte subpopulations (Th1, Th2, Th17 and Th22), as well as increased eosinophils and IgE in blood (3,27). However, the detailed underlying mechanisms, as well as the absolute magnitude of the risks of AD remain largely unknown (2,3,27). For instance, the impact of gene-environment interactions upon epidermal barrier destruction and the resultant variations in clinical presentations have not yet been clearly demonstrated (5). In addition, AD is considered to be an initiating factor for other atopic disorders, including food allergies, allergic asthma and rhinitis, which can continue for a long period of time, maintaining a relapsing-remitting status in affected patients (6). In general, the systematic and precise clarification of AD-associated epidemiologic features, clinical phenotypes, genetic subtype, clinical remission and the underlying pathogenic mechanisms are not yet fully understood (5,27). As a consequence, even though current treatment modalities, including pharmacological-associated interventions alone or in combination with non-pharmacological strategies may be able to relieve pain in patients with moderate to severe AD, their effectiveness is not satisfactory due to the complexity and indeterminacy of the underlying pathogenesis. For example, a recent advancement has been made in the monoclonal antibody (mAb), dupilumab, which has exhibited satisfactory effectiveness against AD with a remission rate of 85% via a subcutaneous administration (11 times) by blocking IL-3 and IL-13 (28). However, in spite of its effectiveness, the accompanied adverse reactions, inconvenience and unexpected clinical outcomes (e.g., headache, injection-site reaction and conjunctivitis), would largely hinder its use in the rational and effective application in patients with AD (29,30).

Distinguishing from the traditional or late-model drug-based strategies, MSC-based cytotherapy has been proven

to be safe and effective against multiple disorders associated with immune abnormalities (31-34). Since the first separation and identification in the 1960s, MSCs have been successfully isolated from adult tissues, perinatal tissues and even derived from human pluripotent stem cells (35-37). Of these, the natural bone marrow- and umbilical cord-segregated MSCs are acknowledged with the most popular and proliferative characteristics, respectively (21,23,24). MSCs function mainly via cytokine paracrine mechanisms [e.g., prostaglandin E2 (PGE2) and transforming growth factor (TGF)- β 1], the inhibition of inflammatory factor production [e.g., interferon (IFN)- γ and tumour necrosis factor (TNF)- α], the recruitment and regulation of other cell constituents (e.g., mast cells, T lymphocytes) and direct differentiation, together with providing a favourable microenvironment (9,38-40). As for the management of AD, by administering a high-dose of hUCB-MSCs (5×10^7) via local subcutaneous injection, Kim *et al* reported few adverse events and a certain improvement of patients with AD with an overall response rate of 55% at week 12 (40).

However, the systemic infusion and long-term effects of MSCs against AD remain unknown. To the best of our knowledge, the present study demonstrates for the first time that hUC-MSCs were effective in the treatment of a patient with AD with other complications, including foot ulcers and a urinary tract infection, leading to a full, rather than partial remission, via a single and convenient intravenous injection. In particular, the severe ulcers and refractory urinary tract infection in the elderly patient with AD were completely eliminated without recrudescence during the 14-month follow-up visit. Simultaneously, according to the systematic clinical and biochemical examinations, and in particular, the tumour-related indicators, the consistent safety and continuous efficacy of MSC-based cytotераpy for AD was confirmed. Nevertheless, more patients with AD need to be enrolled and examined in order to evaluate the reliability and validity of hUC-MSC infusion via intravenous injection. Overall, the data presented herein provide a paradigm and prospect for further investigations towards AD treatment, and may help to predominantly ameliorate the refractory disorder in the future.
