Human dermal fibroblasts were exposed to TGF- $\beta$ 1 (positive control), Gal-1 or Gal-3 for 48 h compared with untreated control (extent of up/downregulation of transcription of genes is given as positive or negative  $\log_2$  fold change). Any change  $>2 \log_2$  fold-change with  $P < 0.05$  (limma moderated t-test) was considered as statistically significant. Gal, galectin; FDR, false discovery rate.
