**Abstract.** Chemotherapeutic agents, including 5-fluorouracil (5-FU), frequently cause intestinal mucositis as a side effect, leading to life quality reduction in colorectal cancer (CRC) patients and interruption of CRC treatment. Traditional Chinese medicines (TCMs) have recently received attention due to their relatively few adverse effects. Pien Tze Huang (PZH), a well-known TCM formulation first documented to have been prescribed >450 years ago, has been demonstrated to be clinically effective in treating various types of cancer including CRC. Although previous studies by our group reported that PZH possesses a variety of anti-cancer activities via multiple mechanisms, it has remained elusive whether it is able to reduce intestinal mucositis induced by 5-FU. The present study evaluated the effect of PZH on 5-FU-induced intestinal mucositis in CT-26 tumor-bearing xenograft mice and investigated the possible molecular mechanism. The results indicated that administration of PZH effectively alleviated the severity of 5-FU-induced diarrhea and morphological intestinal damages, but had no significant effect on body weight loss. In addition, a terminal deoxynucleotidyl transferase dUTP nick end labeling assay revealed that PZH treatment significantly inhibited cell apoptosis in the intestinal crypt. Furthermore, immunohistochemical staining showed that PZH treatment reduced the protein expression of pro-apoptotic B-cell lymphoma 2 (Bcl-2)-associated X protein but enhanced that of anti-apoptotic Bcl-2 in the intestinal crypt. Taken together, the results of the present study suggested that PZH effectively attenuates 5-FU-induced intestinal mucositis, which is in part associated with its inhibitory effect on cell apoptosis in the intestinal crypt.

**Introduction**

Colorectal cancer (CRC) poses a significant threat to human health and is the second most commonly diagnosed cancer in females and the third in males, with an estimated 1.4 million new cases and 693,900 deaths occurring in 2012 worldwide (1). The incidence of CRC is increasing due to smoking, lack of physical activity, overweight and obesity, unhealthy diet and excessive alcohol consumption (2). Chemotherapy is currently a major post-operative adjunctive or preferred therapy for patients with CRC in intermediate and advanced stages. 5-Fluorouracil (5-FU)-based chemotherapy is the most widely prescribed treatment for CRC in clinical practice (3). However, normal cells, tissues and their functions are inevitably injured by 5-FU, which disrupts the balance of the body’s self-regulatory system (4,5). The major side effects of 5-FU include intestinal mucositis, myelosuppression and immunosuppression (6). It has been reported that ~80% of cancer patients who have received 5-FU treatment displayed clinical manifestations of intestinal mucositis, such as severe diarrhea, mal-absorption, vomiting and bleeding (7,8). The side effect not only forces certain patients to completely abandon the treatments, but also markedly affects their quality of life.

The pathogenic mechanisms of 5-FU-induced intestinal mucositis are complex and heterogeneous, including direct toxicity, apoptosis, hypo-proliferation, oxidative stress and abnormal inflammation (9-11). In particular, cell apoptosis has a critical role in the intestinal mucositis induced by 5-FU. Clinical studies and animal experiments have demonstrated that a large amount of apoptotic cells were observed in the intestinal crypt prior to serious mucosal destruction after 5-FU treatment (12,13). Apoptosis is triggered by proteolytic...
enzymes such as caspases, a family of cysteine proteases that act as common death effector molecules (14). Activation of caspases may be initiated through two signaling pathways, the intrinsic (mitochondrial) pathway and the extrinsic (death-receptor) pathway (15,16). The intrinsic pathway is generally activated when pro-apoptotic proteins such as B-cell lymphoma 2 (Bcl-2)-associated X protein (Bax) are released from the mitochondria. In addition, it has been shown that apoptosis induced by 5-FU at high doses (130-200 mg/kg) is accompanied by an alteration of Bax and Bcl-2 expression, indicating the activation of the intrinsic apoptotic pathway (12,13).

Traditional Chinese Medicine (TCM), as an important complementary and alternative medicine, evolved over thousands of years with its own unique system of theories, diagnostics and therapies in China and Southeast Asia. TCM has a number of benefits, such as having relatively few side effects, the capacity to decrease negative side effects associated with chemotherapy, enhancement of the effects of conventional cancer treatments, and improvement of patients' quality of life and immune function (17). Therefore, TCM has been increasingly used in conjunction with chemotherapies to improve the clinical management of patients with cancer. Pien Tze Huang (PZH) is a well-known TCM formulation, the prescription of which was first documented by a royal physician >450 years ago during the Chinese Ming Dynasty. PZH has been used in China for centuries as a folk remedy for various cancer types, including CRC. Although previous studies by our group reported that PZH possesses a variety of anti-cancer activities via multiple mechanisms (18-30), it has remained elusive whether PZH reduces intestinal mucositis induced by 5-FU. The present study evaluated the effect of PZH on 5-FU-induced intestinal mucositis in CT-26 tumor-bearing xenograft mice and investigated the possible molecular mechanism.

Materials and methods

Materials and reagents. RPMI-1640 medium, fetal bovine serum (FBS), penicillin-streptomycin and trypsin-EDTA were purchased from Thermo Fisher Scientific, Inc. (Waltham, MA, USA). Matrigel was obtained from BD Biosciences (San Jose, CA, USA). Bcl-2 (cat. no. ART1069) and Bax (cat. no. ARE6007) antibodies were provided by Antibody Revolution Inc. (San Diego, CA, USA) and horseradish peroxidase (HRP)-conjugated secondary antibodies (cat. no. Kit-0017) were obtained from Maxinx Corp. (Fuzhou, Fujian, China). Harris' hematoxylin was obtained from Solarbio Corp. (Beijing, China). A terminal deoxynucleotidyl transferase-mediated dUTP nick end labeling (TUNEL) assay kit was purchased from Keygen Biotech (Nanjing, China).

Preparation of PZH. PZH was obtained from and authenticated by the sole manufacturer Haipu Pharmaceutical Co., Ltd. (Zhangzhou, China; Chinese Food and Drug Administration approval no. Z35020242). Stock solutions of PZH were prepared immediately prior to use by dissolving the PZH powder in saline to a concentration of 25 mg/ml and sonication for 30 min. The sample was ready for intragastric infusion when the powder was completely dissolved and the solution became clear.

Preparation of 5-FU. 5-FU was obtained from the Xudong Haipu Pharmaceutical Co., Ltd. (Shanghai, China). Immediately prior to use, 5-FU was dissolved in saline to a concentration of 15 mg/ml.

Cell culture. The CT-26 murine colon carcinoma cell line was purchased from the Shanghai Cell Bank of the Chinese Academy of Sciences. The cells were grown in RPMI-1640 medium containing 10% (v/v) FBS, 100 U/ml penicillin and 100 µg/ml of streptomycin in a humidified incubator at 37°C in an atmosphere containing 5% CO2.

Animals. A total of 32 male BALB/c mice (initial body weight, 20-22 g, 4-6 weeks old), obtained from Shanghai SLAC Laboratory Animal Co., Ltd. (Shanghai, China), were allowed to acclimatize for two days and were housed in a specific pathogen-free environment with food and water supplied ad libitum throughout the experiment. The environment was maintained at 22°C with a 12-h light/dark cycle. All the animal treatments were performed in compliance with international ethical guidelines and the National Institutes of Health Guidelines for the Care and Use of Laboratory Animals. The experiments were approved by the Institutional Animal Care and Use Committee of Fujian University of Traditional Chinese Medicine (Fuzhou, China).

Establishment of mice xenografted with CT-26. After detachment through trypsinization with trypsin-EDTA, CT-26 cells were re-suspended in serum-free RPMI-1640. A total of 2x10⁶ cells mixed with Matrigel (1:1) were subcutaneously injected into the right flank region of each mouse. When the tumor size reached 300-350 mm², the mice were randomly divided into 4 groups (n=8 in each): Control group, PZH group, 5-FU group and 5-FU + PZH group. 250 mg/kg of PZH was orally administered daily for 4 days, while 5-FU (150 mg/kg) was intraperitoneally administered only on the first day of treatment. The body weight was measured every day. At the end of the experiment, mice were sacrificed by cervical dislocation. The jejunum was excised for further analyses.

Mucositis assessment. Disease severity was assessed daily by monitoring body weight and scoring for diarrhea. Diarrhea score was calculated based on the consistency of stools, using the modified parameters as previously described (31): 0, normal (normal stool or absent); 1, slight (slightly wet and soft stool); 2, moderate (wet and unformed stool with moderate perianal staining of the coat); 3, severe (watery stool with severe perianal staining of the coat).

Intestinal morphometry and histopathological assessment. A segment of the jejunum (3-cm segment immediately distal to the ligament of Treitz) was taken. Specimens were fixed in 4% paraformaldehyde for 24 h, embedded in paraffin, sectioned at 4 µm and stained with haematoxylin and eosin (H&E). Morphological assessment was performed by measuring the change in jejunum villus height (from the top
of the villus to the villus-crypt junction) and crypt depth (defined as invagination depth between adjacent villi) using a light microscope and images were captured at a magnification of x100 and x400. The shortening of villi was evaluated by the average villus-to-crypt ratio. Ten intact and well-oriented villi and crypts were measured and averaged in longitudinal tissue sections for each sample.

Histopathological assessment was performed by using a modification of the histopathological scores described by Macpherson and Pfeiffer (32) and was graded as follows: 0, normal histological findings; 1, mucosa: Villus blunting, loss of crypt architecture, sparse inflammatory cell infiltration, vacuolization and edema, but normal muscular layer; 2, mucosa: Villus blunting with fattened and vacuolated cells, crypt necrosis, intense inflammatory cell infiltration, vacuolization and edema, but normal muscular layer; 3, mucosa: Villus blunting with fattened and vacuolated cells, crypt necrosis, intense inflammatory cell infiltration, vacuolization and edema, and muscular layer: Edema, vacuolization, sparse neutrophil infiltration.

**TUNEL assay.** The 4-µm-thick sections of jejunum samples were analyzed by TUNEL staining using an in situ apoptosis detection kit. Apoptotic cells were counted as diaminobenzidine (DAB)-positive cells (brown staining) at five arbitrarily selected microscopic fields at a magnification of x400 under a light microscope.

**Immunohistochemistry (IHC) assay.** IHC staining for Bcl-2 and Bax was performed to assess apoptotic signaling. In brief, the jejunum samples were fixed with 4% paraformaldehyde for 24 h, embedded in paraffin and cut into 4-µm sections. The sections were subjected to antigen retrieval and the endogenous peroxidase activity was quenched with hydrogen peroxide. After blocking non-specific proteins, the sections were incubated at 4°C overnight with primary antibodies against Bcl-2 (dilution, 1:400) and Bax (dilution, 1:400). After being washed with PBS, the slides were stained with a HRP-conjugated secondary antibodies and then washed with PBS. The slides were then incubated with DAB as the chromogen, followed by counterstaining with diluted Harris’ hematoxylin. After staining, five high-power fields (magnification, x400) were randomly selected for each slide and the average proportion of Bcl-2 and Bax-positive cells in each field was counted using the True Color Multi-Functional Cell Image Analysis Management System (Image-Pro Plus; Media Cybernetics, Rockville, MD, USA). To exclude any non-specific staining, PBS was used to replace the primary antibody as a negative control.

**Statistical analysis.** Values are expressed as the mean ± standard error of the mean of six animals per group and were analyzed using the SPSS package for Windows (version 18.0; SPSS, Inc., Chicago, IL, USA). Statistical analysis of the data was performed with Student’s t-test and analysis of variance. P<0.05 was considered to indicate a statistically significant difference.

**Results**

**PZH alleviates 5-FU-induced diarrhea in CT-26 tumor-bearing mice.** Since body weight is a widely used indicator and diarrhea is the most common clinical symptom for the evaluation of 5-FU-induced intestinal mucositis (33,34), the present study assessed body weight changes and diarrhea in CT-26 xenograft mice after treatment with 5-FU and/or PZH. As shown in Fig. 1A, 5-FU challenge significantly reduced the body weight in tumor-bearing mice as compared with that in the controls and caused serious diarrhea. Although PZH did not neutralize body weight loss caused by 5-FU, it significantly alleviated 5-FU-induced diarrhea in the experimental animals (Fig. 1B). PZH alone did not result in body weight loss and diarrhea during the course of the experiment.

**PZH ameliorates 5-FU-induced histopathological changes in the intestine of CT-26 tumor-bearing mice.** The histopathological changes in jejunum tissues were examined by H&E staining. As presented in Fig. 2A, compared with mice in the control or PZH only group, 5-FU-treated mice displayed severe tissue damage in the jejunum, including villus deformation,
loss and atrophy, loss of normal crypt architecture, intense inflammatory cell infiltration, vacuolization and oedema (arrows). However, administration of PZH significantly ameliorated 5-FU-induced intestinal damage in tumor-bearing mice (Fig. 2B-D). These observations were verified by histopathological assessment, where the microscopic scores after...
administration of 5-FU with or without PZH were 2.9 and 1.4, respectively (P<0.05; Fig. 2E).

**PZH inhibits 5-FU-induced apoptosis of intestinal crypt cells in CT-26 tumor-bearing mice via modulation of Bcl-2 and Bax protein expression.** Apoptosis is the critical factor in the occurrence of intestinal mucositis induced by 5-FU (22); therefore, a TUNEL assay was performed in order to analyze the effect of PZH on the apoptosis of intestinal crypt cells induced by 5-FU. As presented in Fig. 3, 5-FU challenge significantly increased the percentage of TUNEL-positive intestinal crypt cells in xenograft mice, as compared with that in the mice in the control or PZH only groups, which, however, was significantly reduced by PZH treatment. In addition, IHC staining revealed that 5-FU significantly reduced the level of the anti-apoptotic protein Bcl-2 in intestinal crypt cells, whereas the level of the pro-apoptotic protein Bax was significantly increased after 5-FU challenge (Fig. 4A-C). However, 5-FU-induced imbalance of the Bcl-2/Bax ratio was reversed by PZH treatment (Fig. 4D).

**Discussion**

5-FU is one of the anti-cancer drugs widely utilized in the treatment of CRC in clinical practice (6). However, continuous use of 5-FU usually has severe toxic effects, particularly intestinal mucositis (12), resulting in discontinuation of cancer chemotherapy and impairment of the quality of life of patients. Therefore, immediate and effective countermeasures to overcome these potential problems are urgently required. TCMs have attracted an increasing amount of attention worldwide, since they have a relatively low toxicity as compared with that of modern chemotherapeutics and have a long history of application in cancer therapy. PZH, a well-known TCM formulation, has long been used as a folk remedy for various cancer types in China and Southeast Asia. Previous studies by our group have demonstrated that PZH possesses a broad range of anti-cancer activities due to its ability to affect multiple intracellular targets, suggesting that PZH may be a novel multi-potent therapeutic agent for the treatment of CRC. In order to further elucidate the beneficial effects of PZH in cancer therapy, the present study evaluated its effect on intestinal mucositis induced by a single dose of 5-FU using a CT-26 CRC xenograft mouse model.

Consistent with the results of previous studies (10-12), administration of 5-FU to mice caused severe intestinal mucositis, which was morphologically characterized by the shortening of villi, destruction of intestinal crypts and intense inflammatory cell infiltration, accompanied by clinical symptoms such as diarrhea and body weight loss. More importantly, it was demonstrated that PZH treatment alleviated the severity of 5-FU-induced morphological intestinal damages and diarrhea, although it had no significant effect on body weight loss.

The pathogenesis of 5-FU-induced intestinal mucositis is remains to be fully elucidated; however, it is considered to be a consequence of several pathogenic elements, including direct toxicity, oxidative stress, apoptosis, hypo-proliferation and abnormal inflammation (19-21). In particular, apoptosis is the critical factor in the occurrence of intestinal mucositis induced
by 5-FU (22). Several studies have indicated that apoptosis of intestinal crypt cells induced by 5-FU is accompanied by increased pro-apoptotic Bax expression and decreased anti-apoptotic Bcl-2 expression (22,23). As expected, the present study we observed that 5-FU challenge significantly promoted cell apoptosis in the intestinal crypt, with the increase of Bax expression and the decrease of Bcl-2 expression. However, administration of PZH inhibited 5-FU-induced apoptosis of intestinal crypt cells through suppression the pro-apoptotic Bax/Bcl-2 ratio.

The aim of this study was to investigate the effect and possible molecular mechanism of PZH on 5-FU-induced intestinal mucositis in CRC tumor-bearing xenograft mice. Meanwhile we observed the changes of tumor volume and weight. The results indicated that compared with the control group, PZH has no significant effect on tumor growth in CRC mice. A previous study by the current authors demonstrated that administration of PZH significantly inhibited CRC growth in vivo when the treatment period of HZH was more than 2 weeks, and the tumor inhibition occurred after 7 days of PZH administration (23). In the current study, PZH administration lasted only 5 days. Therefore, PZH didn't show inhibitory effect on the growth of CT-26 cell xenograft, but this have been asso
ciated with the shorter administration time of PZH.

In conclusion, the findings of the present study suggested that PZH may be a promising candidate for an adjuvant drug to help ameliorate the adverse effects of currently used modern chemotherapeutics.
