Abstract. Phytocomponent \( p \)-hydroxycinnamic acid (HCA) has been shown to have stimulatory effects on bone calcification and inhibitory effects on bone resorption in rat femoral tissues \textit{in vitro}. Whether HCA has a stimulatory effect on mineralization in osteoblastic cells is unknown. This study was undertaken to determine the effect of HCA on mineralization in osteoblastic MC3T3-E1 cells \textit{in vitro}. Cells were cultured for 72 h in a minimum essential medium (\( \alpha \)-MEM) containing 10\% fetal bovine serum (FBS), and the cells with sub-confluency were changed to a medium containing either vehicle or HCA (10\(^{-7}\)-10\(^{-5}\) M) without FBS. Culture with HCA (10\(^{-7}\)-10\(^{-5}\) M) did not have a significant effect on cell proliferation and cell death. Deoxyribonucleic acid (DNA) content in osteoblastic cells was significantly increased after culture with HCA (10\(^{-6}\) or 10\(^{-5}\) M) for 48 or 72 h. Alkaline phosphatase activity in osteoblastic cells was significantly increased after culture with HCA (10\(^{-7}\)-10\(^{-5}\) M) for 24, 48, or 72 h. The results with Alizarin red staining for calcium showed that mineralization was significantly stimulated after culture with HCA (10\(^{-8}\)-10\(^{-5}\) M) for 7, 14, or 21 days. This study demonstrates that HCA has stimulatory effects on mineralization in osteoblastic MC3T3-E1 cells.

Introduction

Osteoporosis with a decrease in bone mass is widely recognized as a major public health problem (1,2). The most dramatic expression of this disease is represented by fractures of the proximal femur. Deficiency of nutrients is after observed in the elderly, and it appears to be more severe in patients with fracture than in the general aging population (3,4). Pharmacological and nutritional factors are needed to prevent bone loss with increasing age (5-7). Bone loss may be due to decreased bone formation and increased bone resorption.

Cinnamic acid is present in many plants. \( p \)-Hydroxycinnamic acid (HCA) is an intermediate metabolic substance in plants, and it is synthesized from thyrosine. HCA is found in turnip tops, corn bran, and oregano (8-10). Among cinnamic acid and other related compounds (including HCA, ferulic acid, caffeic acid, and 3,4-dimethoxycinnamic acid), HCA has unique anabolic effects on bone components (11). HCA has been found to have stimulatory effects on bone formation and inhibitory effects on bone resorption in rat femoral tissues \textit{in vitro} (11). HCA has potent inhibitory effects on osteoclast-like cell formation in mouse bone marrow cultures \textit{in vitro} (12). The intake of HCA is found to have anabolic effects on bone components in the femoral tissues of normal rats (13), inhibitory effects on bone loss in diabetic rats administered with streptozotocin (14), and preventive effect on bone loss in ovariectomized rats (15). HCA may have a role in the prevention of osteoporosis with aging.

Whether HCA has anabolic effects on osteoblastic cells that are involved in bone formation and mineralization has not been clarified. This study was undertaken to determine the effect of HCA in osteoblastic MC3T3-E1 cells \textit{in vitro}. We found that HCA stimulates mineralization in osteoblastic cells \textit{in vitro}.

Materials and methods

Chemicals. \( \alpha \)-minimal essential medium (\( \alpha \)-MEM) and penicillin-streptomycin (5,000 U/ml penicillin; 5,000 \( \mu \)g/ml streptomycin) were obtained from Gibco Laboratories. Fetal bovine serum (FBS) was obtained from Bioproducts, Inc. \( p \)-Hydroxycinnamic acid (HCA) and alizarin red S was purchased from Sigma (St. Louis, MO, USA). Other chemicals were of reagent grade and were obtained from Wako Pure Chemical Industries (Osaka, Japan). All water used were glass distilled.

Cell culture. Osteoblastic MC3T3-E1 cells were cultured at 37\(^\circ\)C in a CO\(_2\) incubator in plastic dishes containing \( \alpha \)-MEM supplemented with 10\% FBS. They were subcultured every 3 days using 0.2\% trypsin plus 0.02\% EDTA in Ca\(^{2+}\)/Mg\(^{2+}\)-free
phosphate-buffered saline (PBS). For experiments, about $1.0 \times 10^5$ cells per dish were cultured for 72 h to obtain subconfluent monolayers in 35-mm plastic containing 2 ml $\alpha$-MEM with 10% FBS. After the cells were rinsed with PBS, the medium was exchanged for medium without FBS containing either vehicle or HCA (10$^{-7}$-10$^{-5}$ M), and the cells were cultured further for 7-21 days. Cell viability was estimated by staining with trypan blue.

**Cell counting.** After trypsinization of the cells in each culture dish using Ca$^{2+}$/Mg$^{2+}$-free PBS containing 0.2% trypsin and 0.02% EDTA for 2 min at 37˚C, cells were collected and wash-centrifuged in a phosphate-buffer saline (PBS) solution at 100 g for 5 min. The cells were resuspended in a 0.5 ml PBS solution, and an aliquot was stained with eosin. The cells were counted under a microscope using a hemacytometer plate. For each dish, we took the average of two counts.

**Biochemical analysis.** To measure DNA content in the cells, the cells were detached using 0.2% trypsin plus 0.02% EDTA in Ca$^{2+}$/Mg$^{2+}$-free PBS and washed with PBS. The cells were shaken with 2.0 ml of ice-cold 0.1 N NaOH solution for 6 h after disruption (16). After alkali extraction, the samples were centrifuged at 10,000 g for 5 min, and the supernatant was collected. DNA content in the supernatant was determined using the method of Ceriotti (17) and expressed as the amount of DNA (μg) per dish.

To determine the protein concentration in osteoblastic cells, the cells were washed three times with PBS, scraped into 0.5 ml of ice-cold 0.25 M sucrose solution, and disrupted for 30 sec with an ultrasonic device. The supernatant, centrifuged at 600 g for 5 min, was used to measure enzyme activity. The enzyme assay described below was carried out under optimal conditions. Alkaline phosphatase activity was determined using the method of Walter and Schutt (19). The enzyme activity was expressed as nanomoles of p-nitrophenol liberated per minute per milligram of protein.

**Alizarin red staining.** Osteoblastic MC3T3-E1 cells (2.5x10$^5$ cells) were cultured for 72 h in $\alpha$-MEM containing 10% FBS. Cells with subconfluency were changed to Dulbecco’s modified essential medium (DMEM) containing ascorbic acid (100 μg/ml) and 4 mM β-glycerophosphate in the presence or absence of HCA (10$^{-8}$ or 10$^{-5}$ M) with 10% FBS. After medium change, cells were cultured for 7, 14, or 21 days. The medium was changed with every 3 days. At each time-point, cells were rinsed with PBS, and fixed on ice with 70% ethanol for 15 min for alizarin red staining of calcium (20). The Alizarin red solution (40 mM, pH 4.2) was filtered through Whatman paper and applied to the fixed wells for 30 min at room temperature. Non-specific staining was removed by several washes in water.

**Statistical analysis.** Data are expressed as the mean ± SEM. Statistical differences were analyzed using Student's t-test. P-values <0.05 were considered to indicate statistically significant differences. Also, we used an ANOVA multiple comparison test to compare the treatment groups.

**Results**

**Effect of HCA on proliferation of osteoblastic MC3T3-E1 cells.** The effect of HCA on proliferation of osteoblastic MC3T3-E1 cells reaching subconfluent monolayer was examined. Osteoblastic cells were cultured for 72 h in a medium containing 10% FBS in the presence or absence of
HCA (10^{-7}-10^{-5} M). The proliferation of osteoblastic cells was progressively increased with culture of 72 h to reach confluent monolayers. This increase was not significantly changed in the presence of HCA (10^{-7}-10^{-5} M) (data not shown). The effect of HCA (10^{-7}-10^{-5} M) on cell number was not observed when the cells with subconfluency were cultured for 24, 48, or 72 h in the absence of 10% FBS (Fig. 1).

**Effect of HCA on biochemical components in osteoblastic MC3T3-E1 cells.** Osteoblastic cells were cultured for 72 h in a medium containing 10% FBS. Cells with subconfluency were cultured for 24, 48, or 72 h in a medium containing HCA (10^{-7}-10^{-5} M) without FBS. The change in DNA content or alkaline phosphatase activity in osteoblastic cells was examined. DNA content in osteoblastic cells was significantly increased after culture with HCA (10^{-6} or 10^{-5} M) for 48 or 72 h (Fig. 2). Alkaline phosphatase activity in osteoblastic cells was significantly increased after culture with HCA (10^{-7}-10^{-5} M) for 24, 48, or 72 h (Fig. 3).

**Effect of HCA on mineralization in osteoblastic cells.** Osteoblastic cells with subconfluency were cultured for 7, 14, or 21 days in a medium containing either vehicle or HCA (10^{-8}-10^{-5} M) to examine the mineralization (Fig. 4). The results with Alizarin red staining for calcium showed that mineralization was significantly stimulated in the presence of HCA (10^{-5}-10^{-3} M). The enhancement of mineralization was observed after 7 days of culture. The effect was markedly enhanced after 21-days of culture with HCA (10^{-5} or 10^{-3} M).
Discussion

Phytocomponent HCA has been shown to have stimulatory effects on bone formation and inhibitory effects on bone resorption in rat femoral tissues in vitro (11). HCA inhibits osteoclastogenesis in mouse marrow culture in vitro (12), suggesting that the compound can inhibit osteoclastic bone resorption. Whether HCA has anabolic effects on osteoblastic cells in vitro was examined. HCA was found to have stimulatory effects on mineralization in osteoblastic MC3T3-E1 cells in vitro.

HCA did not have a significant effect on cell proliferation of osteoblastic cells in reaching subconfluent monolayers (data not shown). Also, the number of osteoblastic cells with subconfluency was not significantly changed after culture with HCA, indicating that the compound does not induce cell death.

Culture with HCA caused a significant increase in DNA content in osteoblastic cells. The effect of HCA in increasing DNA content in osteoblastic cells was seen in the absence of FBS. It is speculated that HCA has a stimulatory effect on DNA synthesis in osteoblastic cells.

Alkaline phosphatase is involved in mineralization in osteoblastic cells (21). The enzyme activity in osteoblastic cells was significantly increased after culture with HCA. It is assumed that HCA stimulates cell differentiation in osteoblastic cells.

The results of Alizarin red stain showed that the prolonged culture with HCA markedly stimulates mineralization in osteoblastic cells. This finding may support the view that culture with HCA induces the differentiation of osteoblastic cells and stimulates mineralization in the cells. HCA caused a significant increase in calcium content in rat femoral tissue culture in vitro (11). Thus, HCA was demonstrated to have stimulatory effects on osteoblastic mineralization.

In conclusion, it has been demonstrated that culture with HCA stimulates mineralization in osteoblastic MC3T3-E1 cells in vitro.
