Abstract. Colonic paracellular permeability is regulated by various factors, including dynamics of the cytoskeleton. Recently, ACF7 has been found to play a critical role in cytoskeletal dynamics as an essential integrator. To elucidate the physiological importance of ACF7 and paracellular permeability, we conditionally knocked out ACF7 in the intestinal mucosa of mice. Histopathological findings indicated that ACF7 deficiency resulted in significant interstitial proliferation and columnar epithelial cell rearrangement. Decreased colonic paracellular permeability was detected using a Ussing chamber and the FITC-inulin method. In order to clarify the underlying mechanism, we further analyzed the expression levels of three important tight junction proteins. Downregulation of ZO-1, occludin and claudin-1 was identified. Immunofluorescence provided strong evidence that ZO-1, occludin and claudin-1 were weakly stained. We hypothesized that ACF7 regulates cytoskeleton dynamics to alter mucosal epithelial arrangement and colonic paracellular permeability.

Introduction

The physiological function of the intestinal barrier regulates selective passage from the gut lumen, i.e. the transport of ions or small molecules but not large molecules and microorganisms (1). The intestinal barrier is composed of both a cellular barrier and a paracellular barrier. The paracellular barrier largely consists of the tight junction (TJ) between epithelial cells (1). The TJ is composed of tight junction proteins (TJPs) which is a group of proteins with various functions and molecular structures. The TJPs regulate the function of the intestinal barrier through their expression level and functional status (2). A change in the levels of TJPs is considered as a marker of impaired intestinal barrier and increased mucosal permeability in many diseases (3).

Previous studies have shown that TJPs are involved in the regulation of intestinal permeability (4). Recently, changes in the cytoskeleton dynamics have also been noted in the alteration of intestinal permeability (5). It has been shown that in the T84 colon cancer cell line, disrupted F-actin results in increased paracellular permeability (6). The regulation of intestinal permeability is a dynamic system in which the mobility of intestinal epithelial cells is critically involved. It has been noted that their interaction is the key to the regulation of intestinal permeability (4). However, little is known concerning the regulation of intestinal paracellular permeability in regard to the interaction among TJPs and cytoskeleton proteins.

Microtubes (MTs) are required for cellular mobility and maintenance of cellular morphology (7). Dynamic cytoskeleton formation by microfilaments and MTs determines cellular mobility and cell shape (8). Kodama et al (9) demonstrated that ACF7 is critically required in MT-microfilament dynamics. ACF7 can stabilize downstream cytoskeleton structure by either direct binding to MTs or forming links between MTs and microfilaments.

In this study, we employed a conditional gene targeting method to ablate the ACF7 gene in colonic mucosa in order to create ACF7-conditional knockout (cKO) mice. We also employed FITC-inulin, an effective tracer for paracellular permeability assay (10). By utilizing a Ussing chamber and FITC-inulin, we confirmed this mouse as a murine model for decreased colonic paracellular permeability. Hematoxylin and eosin (H&E) staining revealed histopathological changes in the mucosal epithelial arrangement and interstitial proliferation. Since TJPs are vital cytoskeletal proteins, we determined the transcription and expression levels of ZO-1, occludin and claudin-1, which are typical members of the TJPs. Our findings revealed that the three TJPs were downregulated in this ACF7-cKO model. Immunofluorescence for the three proteins also found weak staining for ACF7 in the cKO mice.

Therefore, based on this significant evidence we hypothesize that ACF7 regulates tight junction protein expression, changes mucosal epithelial arrangement and consequently alters colonic paracellular permeability.

Materials and methods

Generation of ACF7-cKO mice. Due to the lethal effect of ACF7 deficiency in conventional knockout models (11), we
crossed ACF7fl/fl mice (12) and Vil-cre transgenic mice to generate cKO mice. ACF7fl/fl mice were kindly donated by Xiaoyang Wu of the Howard Hughes Medical Institute and Laboratory of Mammalian Cell Biology and Development, Rockefeller University, New York, NY, USA. B6.SJL-Tg(Vil-cre)997Gum/J mice of C57BL/6 background were purchased from Jackson Laboratory (Bar Harbor, ME, USA).

Vil-cre transgenic mice were identified by PCR using DNA extracted from the peripheral blood of 4-week-old transgenic mice using PCR primers: forward, 5'-GTGTGGGACAGAGAACAAACC-3' and reverse, 5'-ACATCTTCACTGGTTGCGG-3'. The PCR reaction generated a 1,100-bp product. Excision efficiency was assessed by PCR using the following primers: upstream, 5'-AAAGAAACGGAAATACTGGCC-3' and downstream, 5'-GCAGCTTAATTCTGCCAAATTC-3'; with 650- and 700-bp PCR products, respectively. ACF7-cKO mice were generated by crossing F2 in a specific pathogen-free (SPF) environment. The Vil-cre and ACF7 genes were synthesized by Sangon Biotech Co., Ltd. (Shanghai, China).

All mice were maintained in an SPF facility with a regular light cycle (12 h light and 12 h dark) at a controlled temperature (23±1˚C) and relative humidity (50%). Food (SCXK 2008-0016; Shanghai Super B&K Laboratory Animal Corp., Ltd., Shanghai, China) and water were freely available to mice throughout the experimental period. The Sixth People's Hospital Animal Care and Utilization Committee Affiliated to Shanghai Jiaotong University approved all experiments relating to ethical standards.

**H&E staining.** Intestinal samples were fixed in 10% formalin for 12 h, and then embedded in paraffin. Sections (3-µm) were stained with H&E and evaluated by a pathologist. Microscopy of x200 and x400 fields was applied to capture typical images using a DSY5000X microscope and Nikon D200 camera.

**Measurement of colonic mucosal paracellular permeability by Ussing chamber and FITC-inulin.** Mice were sacrificed at 8-12 weeks of age by cervical dislocation. The proximal segment of the colon was dissected, of which the mucosa was stripped from the muscular layer within 10 min. The mucosa was mounted in Lucite chambers exposing the mucosal and submucosa surfaces to 10 ml of oxygenated Krebs buffer. The buffer was maintained at 37˚C by a heated water jacket and circulated by CO2/O2 (13).

Non-absorbable tracer molecule FITC-inulin (1.0 mg/ml) (MW 5,000 kDa) (Sigma-Aldrich, USA) was added to the mucosal side with a spread mucosa area of 0.3 cm². Buffer samples of 200 µl from the submucosal side were collected at 30, 60, 90 and 120 min, and samples were analyzed for fluorescence in black walled 96-well plates (Greiner, Germany) using a Varioskan Flash Scanner (Thermo Scientific, Finland) with excitation at 485 nm and emission at 530 nm (14,15).

**RNA extraction and qRT-PCR.** ACF7-cKO and ACF7fl/fl mice were sacrificed at 12 weeks of age by cervical dislocation. A segment of the colon was dissected at 1.5 cm distal to the cecum. Each colon sample was scissored to expose its interior on clean slides. The mucosa was scraped from the muscular layer and preserved in RNAlater (Invitrogen, USA) solution at -20˚C for further analysis.

We used qRT-PCR to estimate the expression of TJPs (ZO-1, occludin and claudin-1). Briefly, 30 mg of the mucosal scraps was homogenized for RNA extraction. RNA was extracted using a total RNA extraction kit (SLNCO, China), followed by reverse transcription using a qPCR-RT kit (Toyobo Co., Ltd., Japan). cDNA was then evaluated by qRT-PCR using Real-Time PCR Master Mix (Funglyn Biotech, Inc., Canada) using the primers (Generay Biotech Co, Ltd., China) listed in Table I. Denaturation, annealing and extension temperatures were set at 95˚C, 60˚C and 68˚C for 30 sec each, respectively, for 40 cycles according to routine procedures.

**Western blot analysis.** Cytoplasmic proteins were extracted from mucosal samples from ACF7-cKO and ACF7fl/fl mice using a nucleic/plasma protein extraction kit (ViaGene, USA). After quantitation, cytoplasmic protein was then separated by SDS-polyacrylamide gel electrophoresis (SDS-PAGE). Samples were separated on 5% SDS-PAGE for ACF7 protein and on 10% SDS-PAGE for ZO-1, occludin and Claudin-1 for 1 h respectively (Bio-Rad, USA) and transferred onto nitrocellulose membranes (Millipore, USA) at 4˚C, 200 mA, overnight for ACF7 and 1 h for ZO-1, occludin and Claudin-1.

F, forward; R, reverse.
The membranes were blocked for 1 h at room temperature in 5% non-fat dried milk, and then incubated with the primary antibody (1:500; Abcam, UK) with continuous gentle agitation overnight at 4˚C. The membranes were then incubated for 1 h with HRP-conjugated secondary antibodies (1:2,000; Beyotime, China) at room temperature, and finally developed by the ECL western blotting system (Thermo Scientific-Pierce, USA).

Immunofluorescence. Colonic tissue sections were incubated with anti-mouse occludin, anti-mouse claudin-1, anti-mouse ZO-1 (1:100; Abcam), and FITC-labeled goat anti-mouse IgG (1:50; Sigma, USA) was used as a secondary antibody. Typical images were captured using a DSY5000X microscope and Nikon D200 camera at a x400 magnification (excitation at 485 nm).

Statistical analysis. Data are presented as means ± SEM. The differences in mRNA levels of ACF7, ZO-1, occludin and claudin-1, between the ACF7-cKO and ACF7[+/+] mice were compared using an unpaired t-test. Differences in the FITC-inulin filtration rates using a Ussing chamber were compared by monofactor ANOVA analysis (GraphPad, Prism, USA). P-value below the level of α=0.05 was considered to indicate a statistically significant result.

Results

Generation of conditional intestinal ACF7-cKO mice. By genotyping, we successfully identified ACF7-cKO mice (Fig. 1A). As expected, the relative level of ACF7 mRNA declined drastically in the colonic mucosa of the ACF7-cKO mice when compared to that in the control ACF7[+/+] mice (0.097-fold; 4.309±0.73 vs. 44.36±11.08) (Data are means ± SEM; P<0.01, unpaired t-test; n=5/group). Western blot analysis of ACF7 in colonic mucosal extracts revealed that ACF7 protein was decreased in the ACF7-cKO mice and that no ACF7 protein was evident in the ACF7-cKO mice. (D) Fluorescence immunostaining showed weak ACF7 expression in the colonic mucosa of the ACF7-cKO mice compared to that in the ACF7[+/+] mice.

Rearrangement of mucosal epithelia and interstitial proliferation as detected by H&E staining. Through H&E staining, we demonstrated interstitial proliferation in the colonic sections of the ACF7-cKO mice. The results also revealed significant mucosal epithelial rearrangement in the ACF7-cKO mice when compared to the control (Fig 2).

Decreased colonic paracellular permeability in ACF7-cKO mice. We found a significant decrease in the colonic FITC-inulin permeability rate between the ACF7[+/+] and ACF7-cKO mice at 30 min (0.083±0.0085 vs. 0.022±0.0086), 60 min (0.104±0.0095 vs. 0.052±0.0066), 90 min (0.116±0.0106 vs. 0.057±0.0057) and 120 min (0.129±0.0106 vs. 0.067±0.0083) (one-way ANOVA test; n=5/group) (Fig. 3).

Decreased occludin, claudin-1 and ZO-1 expression in ACF7-deficient colonic mucosa. Compared to controls, the relative quantitative value of mRNA expression of ZO-1, occludin and claudin-1 was significantly lower in the ACF7-cKO mice by 2.65-fold (16.79±2.146 vs. 6.33±1.482, Fig. 4A), 7.22-fold (348.4±95.35 vs. 48.27±5.889, Fig. 4B) and 3.62-fold (1.990±0.104 vs. 0.550±0.157, Fig. 4C), respectively (unpaired t-test; n=5/group). Western blot analyses of the TJP, ZO-1, occludin and claudin-1, revealed a decrease in ZO-1,
occludin and claudin-1 expression in the colonic tissues of the ACF7-cKO mice vs. the ACF7^{fl/fl} mice (n=5/group) (Fig. 4D). Immunofluorescence staining further demonstrated that ZO-1, occludin and claudin-1 were significantly downregulated in the colonic mucosa of ACF7-cKO mice compared to levels in the ACF7^{fl/fl} mice (Fig. 4E).

**Discussion**

ACF7 has recently been identified as a key integrator in cellular skeleton dynamics and cell mobility (16). Gene knockdown in an animal, and observation of the entire animal phenotype are the most effective methods of investigation of gene function (17-19). As gene knockout plays an important role during development, traditional knockout sometimes leads to the death of the embryo. Therefore, cKO utilizing the Cre-loxP strategy may avoid this problem (20). Since the ACF7^{-/-} mouse displays fetal lethality (11), we chose to establish a colonic mucosa ACF7-cKO mouse model. Results of our Ussing chamber study indicated a significant decrease in the colonic mucosal permeability in ACF7-cKO mice. H&E staining of the colonic mucoca indicated a positive association between the microscopy findings and cytoskeleton dysregulation. By H&E staining, we observed that epithelial arrangement was disturbed in the ACF7-deficient colonic mucosa, and we hypothesized that cytoskeleton dysregulation results in an alteration of colonic paracellular permeability. Ussing chamber and FITC-inulin results of the colonic paracellular permeability were also correlated with qRT-PCR, western blotting and immunofluorescence results for ZO-1, occludin and claudin-1. The significant decrease in these proteins indicated that TJPs were correlated with ACF7 expression.

The interaction of epithelial TJPs with cytoskeleton proteins has been recognized as essential. The tight junctions can rapidly adapt, in response, to diverse external signals via structural and functional linkage between TJPs and cytoskeleton proteins (21). Tight junctions are the most apical organelles of the apical junctional complex and are primarily involved in the regulation of paracellular permeability. Although previous researches have concerned with the individual molecules of the tight junctions as well as their mutual interactions. Only recently has it been noted to what extent TJPs are important for the regulation of intestinal permeability and which proteins are involved.

Occludin, claudin-1 are transmembrane proteins. They are critically involved in the regulation of the TJ barrier (22). Previous studies have shown that the expression of occludin and claudin-1 is tightly associated with intestinal paracellular permeability (23). Occludin expression levels correlate with
the number of tight junction strands in varied colonic epithelia permeability. Occludin was found to be associated with permeability for ions and small solutes in siRNA experiments (24). In contrast, the role of occludin in intestinal paracellular permeability has not been recognized until one report revealed that occludin-deficient mice exhibit normal epithelial and paracellular permeability (25). The family of claudin proteins consists of a number of essential components associated with deleterious barrier impairment in the event of their deficiency (26). For example, claudin-1-deficient mice died within 24 h of birth, and further study found dramatic fluid and electrolyte loss through intestinal mucosa and skin (27). It has been shown in inflammatory bowel disease (IBD) that decreased ZO-1 expression is associated with intestinal paracellular permeability (28). ZO-1 is a peripheral membrane protein that binds to both the C terminal of occludin and F-actin, thus stabilizing the cytoskeleton structure (29). ZO-1 connects to strand-forming TJs with cytoskeletal proteins (actin and microfilaments) (30). One animal model with upregulation of TJs showed a decrease in intestinal paracellular permeability under GvHD condition (31). Thus, there are different points of view and some are paradoxical.

The previously mentioned studies reflect one important fact. Since these models are established on a complex physiological shock condition and lack long-term homeostasis, the results are varied. Thus, we chose to establish ACF7-knockout mice instead, generating a homogeneous and stable model with which to provide strong evidence for a change in paracellular permeability. Consequently, based on these findings, ACF7 alters the mucosal epithelial arrangement, colonic paracellular permeability and regulates tight junction protein expression. The ACF7-cKO mouse is a suitable model with which to study intestinal permeability regulatory mechanisms and related diseases.
