Abstract. Consequences of deregulated protein N-glycosylation on cancer pathogenesis are poorly understood. TUSC3 is a gene with a putative function in N-glycosylation, located on the short arm of chromosome 8. This is a chromosomal region of frequent genetic loss in ovarian cancer. We established recently that the expression of TUSC3 is epigenetically decreased in epithelial ovarian cancer compared to benign controls and provides prognostic information on patient survival. Therefore, we analyzed the consequences of silenced TUSC3 expression on proliferation, invasion and migration of ovarian cell lines. In addition, we performed subcellular fractionation, co-immunofluorescence and co-immunoprecipitation experiments to establish the molecular localization of TUSC3 in ovarian cancer cells. We demonstrated that TUSC3 is localized in the endoplasmic reticulum as a subunit of the oligosaccharyltransferase complex and is capable of modulation of glycosylation patterning of ovarian cancer cells. Most importantly, silencing of TUSC3 enhances proliferation and migration of ovarian cancer cells in vitro. Our observations suggest a role for N-glycosylating events in ovarian cancer pathogenesis in general, and identify TUSC3 as a tumor suppressor gene in ovarian cancer in particular.

Introduction

Epithelial ovarian cancer is the most lethal gynecologic malignancy and the fourth most frequent cause of cancer mortality in women in western industrialized countries (1). Early detection and diagnosis of ovarian cancer presents one of the challenges of this entity and consequently a majority of cases are diagnosed in advanced stages (FIGO III and IV). The prognosis for women with advanced ovarian cancer remains bleak despite the advances of surgical and medical therapies in the last decades. A better understanding of the pathogenesis of ovarian cancer may lead to earlier diagnosis and novel therapies for this disease.

Tumor suppressor candidate 3 (TUSC3), originally named N33, was identified as a potential tumor suppressor gene in prostate cancer located on chromosome band 8p22 (2,3). Homozygous deletions of this chromosomal region have been detected in pancreatic (4,5) and prostate cancer cell lines (6,7), even though mutations of the TUSC3 coding sequence are rare. Using a systematical screening approach, we recognized TUSC3 as a significantly downregulated gene in ovarian cancer (8). Recently, we revealed a strong prognostic significance of epigenetic silencing of TUSC3 on survival of ovarian cancer patients (9), however, the molecular mechanism of tumor-suppressor effect of TUSC3 on cancer cells remained unclear. TUSC3 deletions or mutations are frequently associated with familial mental retardation syndromes (10,11). TUSC3 function in regulation of magnesium transport and embryonic development in vertebrates has been suggested (12). TUSC3 shares a high sequence homology with Ost3p, a subunit of the oligosaccharyltransferase (OST) complex involved in N-glycosylation of proteins in Saccharomyces cerevisiae (13-15), implying an analogous function in mammalian cells. Alterations of protein N-glycosylation are associated with carcinogenic properties, such as invasion and metastasis (16-18). Deregulated enzymatic activities of proteins directly involved in N-glycosylation, or the availability of potential glycosylation sites determined by the branching of N-glycans are considered to be crucial for these effects (19-21). Well known targets for differential N-glycosylation in tumor cells or their microenvironment are, among others, growth factor receptors (21,22), immunomodulators (23) or extracellular matrix receptors, such as integrins (24).

In this study, we investigated the subcellular localization of TUSC3 in human ovarian cancer cell lines and identified it as a binding partner of STT3A, a core protein of oligo-
saccharyltransferase complex in endoplasmic reticulum in vitro. Additionally, we observed that silencing of TUSC3 expression in vitro stimulates migration and proliferation of ovarian cancer cell lines, in particular under conditions of growth factor deprivation. Taken together, we present the first experimental evidence that a protein involved in N-glycosylation may act as a clinically-relevant tumor suppressor gene in ovarian cancer.

Materials and methods

Cell culture and lentiviral transduction. The cancer cell lines were obtained from American Type Culture Collection and cultured in medium (HEK293T, H134, DMEM; OVCA-R-3, α-MEM; SKOV3, McCoy’s 5A; TR-170, RPMI-1640) enriched with 10% FCS (fetal calf serum), 50 U/ml penicillin G and 50 µg/ml streptomycin sulfate at 37°C in a humidified atmosphere with 5% CO₂. For the reconstitution of TUSC3 expression in H134 cell line, the CDS of the IMAGE clone (B010370 in pDNR-LIB) was cloned into the expression vector pLP-IRESneo. The FLAG peptide was cloned in frame behind the C-terminus of TUSC3 to form a TUSC3-FLAG fusion protein. The empty vector pLP-IRESneo was used as a control. Transfection was performed with Lipofectamine 2000 (Invitrogen), stable clones were selected with G418 (700 µg/ml). Downregulation of TUSC3 in SKOV3 and TR-170 cell lines was performed by lentiviral transduction using a 4-plasmid system with pLKO.1 puro vector containing TUSC3 shRNA or scrambled control (Open Biosystems, Thermo Fisher Scientific) and HEK-293T packaging cell line. To generate stable cell lines, cells were selected in media containing puromycin (3 µg/ml). Prior to the proliferation, migration and invasion assays, cells were cultivated in the absence of selection antibiotics and the status of TUSC3 silencing was assessed by qRT-PCR regularly.

RNA isolation, cDNA synthesis and quantitative real-time RT-PCR. Total RNA from cancer cell lines was prepared using the RNNeasy Mini kit (Qiagen) and quality/quantity assessed on RNA Nano Chips (Lab-on-a-Chip, Agilent Technologies). cDNA was synthesized from 1 µg DNase I-digested total RNA using Random Hexamers (Applied Biosystems) as described elsewhere (8,25) and expressed in relative ratio units. All PCR reactions were performed in 96-well format using Cell Titer-Blue Proliferation, migration and invasion assays. Cells were cultured in medium (HEK293T, H134, DMEM; OVCAR-3, α-MEM; SKOV3, McCoy’s 5A; TR-170, RPMI-1640) enriched with 10% FCS (fetal calf serum), 50 U/ml penicillin G and 50 µg/ml streptomycin sulfate at 37°C in a humidified atmosphere with 5% CO₂. For the reconstitution of TUSC3 expression in H134 cell line, the CDS of the IMAGE clone (B010370 in pDNR-LIB) was cloned into the expression vector pLP-IRESneo. The FLAG peptide was cloned in frame behind the C-terminus of TUSC3 to form a TUSC3-FLAG fusion protein. The empty vector pLP-IRESneo was used as a control. Transfection was performed with Lipofectamine 2000 (Invitrogen), stable clones were selected with G418 (700 µg/ml). Downregulation of TUSC3 in SKOV3 and TR-170 cell lines was performed by lentiviral transduction using a 4-plasmid system with pLKO.1 puro vector containing TUSC3 shRNA or scrambled control (Open Biosystems, Thermo Fisher Scientific) and HEK-293T packaging cell line. To generate stable cell lines, cells were selected in media containing puromycin (3 µg/ml). Prior to the proliferation, migration and invasion assays, cells were cultivated in the absence of selection antibiotics and the status of TUSC3 silencing was assessed by qRT-PCR regularly.

Western blotting and immunoprecipitation. Harvested cells were washed two times with 1X PBS and resuspended in the NP-40 lysis buffer containing 50 mM Tris-Cl (pH 7.4), 150 mM NaCl, 2 mM EDTA, 1% NP-40, 50 mM NaF and supplemented with phosphatase inhibitor cocktail (PhosStop, Roche) and protease inhibitor cocktail (Complete, Roche). Protein extracts (15 µg) quantified by BCA protein assay (Pierce, Austria), were mixed with 2X Laemmlı sample buffer (100 mM Tris pH 6.8, 4% SDS, 200 mM DTT, 20% glycerol and 0.1% bromophenol blue) boiled for 3 min and resolved by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). For analysis of glycosylation of integrin β1, the 7% SDS-PAGE was employed. The resolved proteins were then electroblotted to the 0.45-µm PVDF membrane (Millipore) and incubated

For direct assessment of cell migration a wound healing assay in a confluent cell monolayer was performed. Wound closure was assessed after 18 h. Representative images out of three independent experiments are shown.

Subcellular fractionation and immunofluorescence. Subcellular fractionation (nuclei, mitochondria, lysosomes, microsomes, and cytoplasm) of H134-TUSC3-Flag cells were performed based on a differential centrifugation protocol (1,000, 9,700, 20,200 and 182,000 g max for aforementioned organelles, respectively (26) after cell lysis with a Potter pestle. The purity of these fractions was analyzed by immunoblotting with antibodies against marker proteins for the respective fractions (nucleus, nucleopoenin p62; mitochondria, cox 5a; lysosomes, none; microsomes, ribophorin I; and cytoplasm, β-actin; Sigma-Aldrich). A mouse monoclonal anti-FLAG M2 antibody (F3165, Sigma-Aldrich) primary antibody against FLAG and a goat secondary anti-mouse HRP-linked antibody (Calbiochem) were used.

Immunofluorescence staining was performed on formaldehyde-fixed H134-TUSC3-FLAG cells with antibodies against FLAG SIGI-25 (F2555, Sigma-Aldrich) and calnexin (polycyonal rabbit antibody, kind gift from E. Ivessa) and counterstained with phallolidin (F-actin). For a morphological overview, the whole cells were stained with hematoxyline/eosin or phallolidin (F-actin)/DAPI (nuclei).

Immunocytochemistry. For immunocytochemical staining, cells were washed two times with 1X PBS and resuspended in the NP-40 lysis buffer containing 50 mM Tris-Cl (pH 7.4), 150 mM NaCl, 2 mM EDTA, 1% NP-40, 50 mM NaF and supplemented with phosphatase inhibitor cocktail (PhosStop, Roche) and protease inhibitor cocktail (Complete, Roche). Protein extracts (15 µg) quantified by BCA protein assay (Pierce, Austria), were mixed with 2X Laemmlı sample buffer (100 mM Tris pH 6.8, 4% SDS, 200 mM DTT, 20% glycerol and 0.1% bromophenol blue) boiled for 3 min and resolved by 10% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE). For analysis of glycosylation of integrin β1, the 7% SDS-PAGE was employed. The resolved proteins were then electroblotted to the 0.45-µm PVDF membrane (Millipore) and incubated
with the indicated primary antibodies diluted 1:500-1:1,000 at 4°C overnight. The blots were developed using horseradish peroxidase-conjugated secondary antibodies (anti-rabbit HRP no. 7074 (Cell Signaling) anti-mouse HRP Ab50043 (Abcam), both 1:4,000 and Immobilon Western HRP substrate (Millipore) according to the manufacturer's instructions.

For co-immunoprecipitation, 150 µg of cell extracts were precleared using NP-40-washed G-protein beads (Sigma-Aldrich). Supernatants were incubated with 5 µl of one of the following antibodies: anti-TUSC3 (Ab65213, Abcam), anti-STT3A (Ab55371, Abcam) or commercially available non-specific mouse or rabbit IgG antibody, at 4°C for 1 h. Then, 25 µl of NP-40-washed G-proteins were added and incubated overnight at 4°C. Pellets were washed four times in NP-40 buffer and resolved by SDS-PAGE.

Statistical analysis. In order to compare the TUSC3 shRNA silenced ovarian cancer cell lines to controls at the specified FSC concentrations, two-way ANOVA model with interaction was used. P-values for pairwise post hoc comparisons were corrected for multiple testing using the Holm-Bonferroni method. P≤0.05 were considered to be statistically significant. All calculations were performed using the SPSS software Version 13.0 (SPSS Inc.).

Results

Loss of TUSC3 promotes cell proliferation and migration in vitro. To investigate the tumor suppressive function of TUSC3 in an ovarian cancer model, we silenced the expression of TUSC3 in two serous ovarian cystadenocarcinoma cell lines (SKOV-3, TR-170) using shRNA. Efficiency of the knock-down was confirmed on both mRNA and protein levels (Figs. 1A and 2A). Consequently, we analyzed the effect of TUSC3 silencing on cell proliferation, migration and invasion conditions, however, we did not detect...
major differences in proliferation between TUSC3 silenced and control cells cultured under optimal conditions (10% FCS) (Fig. 1B and 2B). To assess their propensity for serum-independent growth, we exposed the cells to stress conditions using varying serum concentrations. Interestingly, the TUSC3 silenced cells gained a significant survival advantage in contrast to controls after 72 h of cultivation in the absence of serum stimulation (Figs. 1B and 2B). This effect could also be observed to a lesser degree at different time intervals (data not shown). As a next step, we used a Matrigel™ based assay in order to assess effects of TUSC3 knock-down on migration and extracellular matrix (ECM) invasion of ovarian cancer cells. While we did not observe any differences in invasive properties of control ovarian cancer cells regardless of attractant concentration (Figs. 1D and 2D), TUSC3 silenced cells displayed increased migration through the insert membrane in both cell lines studied (Figs. 1C and 2C). These results were further supported by a wound healing assay, showing increased migration and consequent enhanced closure of the epithelial monolayer of SKOV-3 cells in no serum or low serum conditions after 18 h (Fig. 3).

**TUSC3 is localized in the endoplasmatic reticulum as a subunit of the OST complex.** The largest part of the data on TUSC3 localization and function is derived from observations of its yeast homologue Ost3p. To determine the subcellular localization of TUSC3 in mammalian cells, we stably transfected the ovarian cancer cell line H134 with a TUSC3-FLAG fusion protein (Fig. 4A). The H134 cell line does not express TUSC3 due to promoter hypermethylation (data not shown). We performed co-immunofluorescence labeling, which revealed a substantial overlap of the TUSC3-FLAG protein and calnexin, an integral protein of the endoplasmic reticulum (Fig. 4B). Further, subcellular fractions derived from the H134 cells (microsomes, soluble cytoplasm, mitochondria, lysosomes, and nuclei) were analyzed for the presence of exogenous TUSC3-FLAG expression and appropriate fraction markers. We observed TUSC3 enrichment in the microsomal fraction that comprises the endoplasmic
The endoplasmic reticulum (ER) and some minor amounts of cytoplasmic membranes (Fig. 4C). Levels of the endogenous TUSC3 protein in ovarian cancer cell lines were not sufficient for detection in the subcellular fractionation protocol. However, our data confirm the predicted subcellular localization of TUSC3 in the endoplasmic reticulum in ovarian cancer.

Within the endoplasmic reticulum, TUSC3 is supposed to function as a subunit of the OST complex. To determine whether TUSC3 indeed physically interacts with OST in human ovarian cancer cells, we performed co-immunoprecipitation experiments using antibodies specific to endogenous TUSC3 and STT3A, a core catalytic protein of the OST complex. We demonstrated a specific interaction between endogenous TUSC3 and STT3A proteins in TUSC3 expressing ovarian cancer cell lines SKOV-3, TR-170 and OVCAR-3 (Fig. 4D) and provided the evidence for TUSC3 localization in mammalian cells.

TUSC3 modulates glycosylation pattern in H134 ovarian cancer cell line. Next, we wanted to investigate whether there is a causative link between TUSC3 and glycosylation of putative molecular targets. As a model molecule we chose integrin β1, a highly glycosylated membrane protein involved in cell adhesion and migration. We employed the H134 with almost null endogenous TUSC3 gene expression and compared it with H134 cell line highly producing exogenous TUSC3 protein. Probing for integrin β1 in H134 total cell extracts on 6% SDS-PAGE revealed bands between 110-150 kDa corresponding to glycosylated integrin β1. As a control, a complete removal of N-glycosylated oligosaccharides was achieved by digestion with PNGase F, resulting in bands of equal mobility at ~80 kDa, consistent with the calculated molecular weight of roughly 85 kDa. Interestingly, H134 cells overexpressing TUSC3 showed a shift in bands intensity towards the higher molecular weight when compared to control H134 cells (Fig. 5). Accordingly, immunohistochemical staining of H134 cells for total sialylated proteins using the Sambucus nigra lectin (SNA) revealed an increase in sialylation in TUSC3-positive cells compared to TUSC3-negative cells (Fig. 6). Staining for integrin β1 was used as a control.

Discussion

We previously identified TUSC3 as a candidate tumor suppressor gene in ovarian cancer by systematically screening the chromosomal region 8p22 for differentially regulated genes (8). Nevertheless, mutational analysis performed in several tumor entities failed to reveal a significant rate of protein disruptive mutations and the interest in TUSC3 gene consequently vanished. Recently, we documented epigenetic silencing of TUSC3 by promoter hypermethylation in various ovarian cell lines and independent cohorts of ovarian cancer patient samples, revealing a strong prognostic potential on survival and indicating a character of tumor-suppressor gene (9). Upregulation of TUSC3 in pancreatic carcinoma cell line MIA-PACA-2 lacking endogenous expression of TUSC3, decreased binding capacity of TUSC3 overexpressing cells to collagen I and prolonged the doubling time (9). However, molecular information on the role of TUSC3 in ovarian cancer is still insufficient.

TUSC3 is the human homologue to S. cerevisiae Ost3p, a non-catalytic subunit of the oligosaccharyltransferase complex (14,15). Analyses of the Ost3p and its yeast parologue Ost6p (human MagT1/IAP) demonstrated their function in regulating glycosylation efficiency (27) and later also uncovered their oxidoreductase activity as well as a possible role in magnesium transport (12). Aberrant glycosylation of proteins can be found in essentially all in vitro cancer models and human cancers, and many glycosylated epitopes constitute tumor-associated antigens (28,29), sustaining a long-standing debate if and how protein glycosylation is involved in tumorigenesis. Recently, global DNA methylation changes in ovarian cancer cells were linked to significant alterations of protein glycosylation (30). Re-expression of epigenetically silenced glycosylation enzymes or their subunits, such as TUSC3, may provide a possible explanation for this effect. Our functional analysis builds upon this hypothesis and adds crucial data to the incremental understanding of the causal connection between TUSC3 expression and cancer. We were able to show the subcellular localization of TUSC3 in the endoplasmic reticulum (ER) and some minor amounts of cytoplasmic membranes (Fig. 4C). Levels of the endogenous TUSC3 protein in ovarian cancer cell lines were not sufficient for detection in the subcellular fractionation protocol. However, our data confirm the predicted subcellular localization of TUSC3 in the endoplasmic reticulum in ovarian cancer.

Within the endoplasmic reticulum, TUSC3 is supposed to function as a subunit of the OST complex. To determine whether TUSC3 indeed physically interacts with OST in human ovarian cancer cells, we performed co-immunoprecipitation experiments using antibodies specific to endogenous TUSC3 and STT3A, a core catalytic protein of the OST complex. We demonstrated a specific interaction between endogenous TUSC3 and STT3A proteins in TUSC3 expressing ovarian cancer cell lines SKOV-3, TR-170 and OVCAR-3 (Fig. 4D) and provided the evidence for TUSC3 localization in mammalian cells.
Figure 5. Western blot analysis of integrin β1 in H134 cell line. Total cell extracts were resolved on 6% SDS-PAGE, electroblotted to PVDF membrane and probed for integrin β1. The 110-kDa band represents the precursor β1-pool in the ER, the 140-150-kDa bands correspond to the mature integrin β1 protein. Treatment of proteins with the PNGase F resulted in one band approximately at the position of the calculated apoprotein mass (~80 kDa). Adjacent to the blots, quantification curves and band density ratios according to β-actin are shown. Representative image is shown.

Figure 6. Immunocytochemical stains for sialylated proteins (Sambucus nigra lectin, SNA) and integrin β1 in either TUSC3-overexpressing or control H134 ovarian cancer model cell line. Cells were formaldehyde-fixed, permeabilized and probed with anti-integrin β1 antibody and biotinylated-SNA, respectively. The staining for integrin β1 was used as an internal control. Cells were counterstained with hematoxylin/eosin. Representative images are shown.
reticulum of ovarian cancer cells, as predicted from its homology to Ost3p. Further, we demonstrate direct physical interaction between TUSC3 and the OST complex catalytic subunit STT3A. Experiments showing changes in overall or protein-specific glycosylation patterns suggest direct functional involvement of TUSC3 in N-glycosylation. In line with the putative function of TUSC3 as a tumor suppressor, we observed enhanced serum-independent cellular proliferation and migration after silencing of TUSC3 in ovarian cancer cell lines and similarly, a mild increase of the doubling time and reduced migration in H134 cell line overexpressing TUSC3 (data not shown). Although these in vitro effects remain relatively modest due to the limitations of a cell culture system, we believe that loss of TUSC3 and consequent aberrant N-glycosylation might have a much greater effect in ovarian cancer progression and metastasis. In light of recent data on N-glycosylation affecting tumor growth in cells with e.g., deregulated PI3K-Akt pathway (22), our results further add to the picture and highlight the possible role of N-glycosylation events in ovarian cancer tumorigenesis.

Taken together, our data are consistent with tumor-suppressive character of TUSC3 published previously (9), but provide the first evidence of a tumor suppressor gene in ovarian cancer involved in protein glycosylation. Although abnormal protein glycosylation is a common event in many cancers, the missing comprehension of its mechanisms and lack of any substantial evidence for causative genetic aberrations are obstructive to development of glycosylation targeted cancer therapies. Defining the molecular function of TUSC3 in ovarian cancer may contribute to understanding the role of N-glycosylation in ovarian cancer and possibly open the door for future drug development.
