Abstract. Dibenzoylmethane (DB), a minor constituent of the root extract of licorice, belongs to the flavonoid family. Hydroxydibenzoylmethane (HDB) and hydroxymethyldibenzoylmethane (HMDB) have an identical structure to DB, but also possess a hydroxyl group and a hydroxyl and methyl group bonded to aromatic rings, respectively. They inhibit cellular proliferation and induce apoptosis in a variety of types of cancer cell, however, the antimetastatic effects of DB, HDB and HMDB on human breast carcinoma cells remain to be elucidated. The present study aimed to clarify the molecular mechanisms underlying the effects of DB and its analogues on phorbol-12-myristate 13-acetate (PMA)-induced MCF-7 cell metastasis. The results revealed that DB, HDB and HMDB inhibited cell migration and invasion. In addition, PMA-mediated MCF-7 cell invasion was inhibited by DB, HDB and HMDB by inhibiting the expression of matrix metalloproteinase (MMP)-9. Rottlerin, a protein kinase C (PKC)δ inhibitor and LY294002, a phosphatidylinositide 3-kinase (PI3K) inhibitor, reduced the PMA-mediated expression of MMP-9 and cell invasion. Furthermore, DB, HDB and HMDB prevented the activation of PKCδ and PI3K by inhibiting their phosphorylation. The present study was the first, to the best of our knowledge, to demonstrate the antimetastatic potential of DB, HDB and HMDB, which decreased cancer cell invasion through the PI3K/PKCδ-mediated MMP-9 pathway.

Introduction

The majority of malignant solid tumors, including breast cancer, proceed to metastases, which is the most frequent cause of cancer-associated mortality (1). Metastasis is the ability of cells to detach from a primary tumor, invade and intravasate into the lymphatic or blood vessels, disseminate in the lymphatic or circulatory systems and initiate the development of new tumor cells in distant organs (2). The migration and invasion of a cancer cell are two crucial steps in metastasis, as proteolytic enzyme degradation of the extracellular matrix (ECM) (3). Matrix metalloproteinases (MMPs) are essential for ECM degradation and remodeling. MMP-9 and MMP-2 are associated with elevated levels of metastasis in several types of cancer, including breast carcinoma, lung carcinoma and melanoma (4). Inhibition of the expression of MMP-9 by MMP-9 antisense and small interfering RNA constructs suppresses the invasiveness and metastatic ability of tumor cells (5,6). The formation of melanoma and lung carcinoma metastases is reduced in MMP-9-deficient mice (7) and the inhibition of MMP-2 and MMP-9 by potential therapeutic agents, such as snake venom metalloproteinase inhibitor BJ46A, apigenin, quercetin and resveratrol, reduces cancer metastasis in vitro and in vivo (8). Therefore, agents possessing the ability to repress the activation of MMP-2 or MMP-9 warrant development to take advantage of their antimetastatic properties.

The phytochemical, dibenzoylmethane (DB), is a constituent of the root extract of licorice (Glycyrrhiza inflata of the family Leguminosae) and has been identified as a promising antimutagenic and anticarcinogenic compound (9-13). DB inhibits S9-mediated mutagenicity of food-derived heterocyclic amine mutagens (9). Furthermore, DB inhibits S9-mediated mutagenicity of food-derived heterocyclic amine mutagens (9). Furthermore, it decreases the formation of DNA adducts following exposure to benzo(a)pyrene, 1,6-dinitropyrene and 7,12-dimethylbenz(a)anthracene (DMBA) (10,11). Dietary DB prevents DMBA-induced mammary carcinogenesis and azoxymethane/dextran sulfate sodium-induced colon carcinogenesis (12,13) and deregulation of the cell cycle by DB has been observed in human prostate carcinoma cells (14). Treatment with DB promotes the apoptosis
of human lung carcinoma cells, epidermoid carcinoma cells and leukemia cells (15-17). Hydroxydibenzoylmethane (HDB) and hydroxymethyl dibenzoylmethane (HMDB) are important DB analogues, which are identical in structure to DB with the exception of a hydroxyl group and hydroxyl and methyl groups on one of the aromatic rings, respectively. They are more potent than DB in inhibiting the proliferation and inducing apoptosis in COLO 205 colorectal carcinoma cells, A431 epidermoid carcinoma cells, A549 lung adenocarcinoma cells and CH27 lung squamous carcinoma cells (15,16,18). However, whether DB, HDB and HMDB are involved in inhibiting cancer metastasis remains to be elucidated. The present study aimed to examine the effects of DB, HDB and HMDB on the metastatic properties of PMA-treated MCF-7 human breast adenocarcinoma cells.

Materials and methods

Cell culture and reagents. The MCF-7 human breast adenocarcinoma cell line (Bioresource Collection and Research Center, Hsinchu, Taiwan) was routinely grown in RPMI-1640 medium (Biological Industries, Kibbutz Beit Haemek, Israel), supplemented with 10% fetal bovine serum (FBS; Biological Industries) at 37°C in an atmosphere of 5% CO2/95% air under saturating humidity. DB, HDB, HMDB, phorbol-12-myristate 13-acetate (PMA) and 3-(4,5-dimethylthiazol-2-yl)-2,5-di-phenyltetrazolium bromide (MTT) were purchased from Sigma-Aldrich (St. Louis, MO, USA). LY294002 was obtained from Merck Millipore (Darmstadt, Germany). Mouse monoclonal MMP-2, mouse monoclonal MMP-9, rabbit polyclonal phosphorylated (phospho)-phosphatidylinositol 3-kinase (PI3K) p85 (Tyr458)/p95 (Tyr499), rabbit polyclonal phospho-protein kinase Cα (Thr505) and mouse monoclonal β-actin antibodies were supplied by Thermo Fisher Scientific, Inc. (Fremont, CA, USA), Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA) and Cell Signaling Technology, Inc. (Beverly, CA, USA), respectively.

MTT cell viability assay. The MCF-7 cells (2x10^4) were seeded into 96-well plates for 24 h prior to treatment with 5, 10, 25, 50 and 100 µM DB, HDB or HMDB, followed by the addition of 10 ng/ml PMA for 24 h. Following the exposure period, the cells were seeded with MTT solution (5 mg/ml) for 4 h. The formazan was solubilized in isopropanol (Merck Millipore) using 0.04 N HCl (Sigma-Aldrich) and measured spectrophotometrically at 595 nm (Synergy™ HT Multi-Detection Microplate Reader; BioTek Instruments, Inc., Winooski, VT, USA).

Migration assay. Cell migration was assessed by a wound-healing assay using a culture insert (19). Briefly, the cells were seeded into the culture insert (ibidi GmbH, Martinsried, Germany) and grown overnight to 100% confluence. Following removal of the culture insert, a cell-free gap was captured and quantified at 12 h, using an Axio Imager A1 microscope and Axio Vision Rel.4.7 software (Carl Zeiss, Göttingen, Germany). Each value was observed from three randomly selected fields and the data are expressed as the mean number of the migrating cell numbers per field.

Invasion assay. A cellular invasion assay was performed in a modified Boyden chamber (GenePure, Taichung, Taiwan) with 8 µm polycarbonate nucleopore filters (Neuro Probe, Inc., Gaithersburg, MD, USA) coated with 250 µg/ml Matrigel (BD Biosciences, San Diego, CA, USA). RPMI-1640 medium containing 2% FBS was added to the lower compartment of the chamber. The cells (2.5x10^5) were resuspended in RPMI-1640 medium without FBS and added to the upper compartment of the chamber in the presence or absence of DB, HDB or HMDB at 25, 50 and 100 µM, or 1 µM rottlerin and 10 µM LY294002, followed by 10 ng/ml PMA for 12 h. Following incubation, the cells were fixed in methanol (Sigma-Aldrich) for 10 min, stained with Giemsa (Merck Millipore) for 30 min and washed with H2O for 3 min. The cells on the upper side of the filters were removed using cotton-tipped swabs and the cells on the underside of the filters were observed and counted under a light microscope (Axio Imager A1).

Gelatin zymography assay. MCF-7 cells were seeded at a concentration of 2x10^5 cells/ml and incubated for 24 h at 37°C. Following incubation, the culture medium was replaced with serum-free RPMI-1640 medium. The cells were treated with 100 µM DB, 50 µM HDB or 25 µM HMDB, followed by 10 ng/ml PMA and the supernatants were collected and subjected to gel electrophoresis on an 8% sodium dodecyl sulfate-polyacrylamide gel electrophoresis (SDS-PAGE) gel containing 0.1% gelatin. Following electrophoresis, the SDS was removed from the gels by incubation with renaturation buffer (2.7% Triton X-100; Amresco LLC, Solon, OH, USA) for 1 h. The gels were gently agitated and incubated at 37°C for 24 h in the developing buffer containing 50 mM Tris-HCl (pH 7.5), 0.2 M NaCl, 0.2% Brij-35 and 5 mM CaCl2 and stained using coomassie brilliant blue (USB Corporation, Cleveland, OH, USA) and destained with destaining solution (7% acetic acid, 5% methanol, Sigma-Aldrich; 88% H2O) for 30 min, respectively. The proteolytic activity of MMP-9 and MMP-2 were observed as clear bands against the blue background of the stained gelatin.

Reverse transcription polymerase chain reaction (RT-PCR). The mRNA was isolated from the cells using TRIzol reagent (MDBio, Inc., Piscataway, NJ, USA) according to the manufacturer's instructions. The synthesis of complementary DNA (cDNA) was performed using the extracted total RNA (3 µg), reverse transcriptase (200 units; Promega Corporation, Madison, WI, USA) and dT15 primers (0.5 µg; MDBio, Inc.) and the reaction mixture was incubated for 90 min at 37°C. For the PCR assay, 0.04 µg cDNA was added to mixture buffer containing 75 mM Tris-HCl (pH 8.8), 20 mM (NH4)2SO4, 0.01% Tween-20 (v/v), 1 mM MgCl2, 0.2 mM dNTPs, 0.5 µM forward and reverse primers and 1 unit Taq DNA polymerase (MDBio, Piscataway, NJ, USA). The PCR was performed as follows: 5 min at 95°C, 36 cycles (30 sec at 5°C; 30 sec at 55°C and 90 sec at 72°C) and 10 min at 72°C using a PC818 program temperature control system.
MOLECULAR MEDICINE REPORTS 11: 4597-4604, 2015

The PCR products were analyzed on a 2% agarose gel. The following primer pairs were used: β-actin (309 bp) forward 5'-AGCGGGAAATCGTGCGT-3' and reverse 5'-CAGGGTACATGGTGGTGC-3'; MMP-2 (346 bp) forward 5'-CTTTGACGGTAAGGACGG-3' and reverse 5'-CTGGAAGCGGAATGGAA-3' and MMP-9 (479 bp) forward 5'-CAACATCACCTATTGGATCC-3' and reverse 5'-CGGGTGTAGAGTCTCTCGCT-3'.

Immunoblotting. To purify the total protein, the cells were harvested and lysed in cold lysis buffer containing 10% (v/v) glycerol, 1% (v/v) Triton X-100, 1 mM sodium orthovanadate, 1 mM EGTA, 10 mM NaF, 1 mM sodium pyrophosphate, 20 mM Tris (pH 7.9), 100 µM β-glycerophosphate, 137 mM NaCl, 5 mM EDTA, 10 µg/ml apro- tinin and 10 µg/ml leupeptin. Equal concentrations of protein were separated on SDS-PAGE gels and then transferred onto polyvinylidene difluoride (PVDF) membranes (Pall Corporation, Ann Arbor, MI, USA). Following blotting, the PVDF membranes were incubated with anti-phospho-PKCδ (Thr505), anti-phospho-PI3K p85 (Tyr458)/anti-phospho-p55 (Tyr199) or anti-β-actin antibodies (dilutions 1:2,500) for 6 h at 4˚C. Following washing with washing solution [50 mM tris-HCl (pH 7.5), 150mM NaCl, 0.1% Tween-20 (v/v)], the secondary antibody labeled with horseradish-peroxidase was added for 1 h at 4˚C. The targeted proteins were visualized using enhanced chemiluminescence (Western Lightning Plus ECL; PerkinElmer, Inc., Waltham, MA, USA).

Statistical Analysis. Data are expressed as the mean ± standard deviation. GraphPad Prism 5 software (GraphPad Software, Inc., La Jolla, CA, USA) was used for statistical analysis. Statistical comparisons were made by a one-way analysis of variance, followed by Dunnett's multiple-comparison test. P<0.05 was considered to indicate a statistically significant difference.

Results

DB, HDB and HMDB reduce PMA-induced MCF-7 cancer cell migration and invasion. To determine whether DB and its analogues were involved in inhibiting the PMA-induced migration of the MCF-7 cells, the cells were treated with PMA and/or DB, HDB or HMDB and migration was assessed using a wound-healing assay. Treatments with DB, HDB and HMDB significantly inhibited PMA-induced cell migration (Fig. 1). Treatment with 25, 50 and 100 µM DB reduced the migration of the cancer cells by 21, 60 and 84%, respectively, compared with those treated with PMA only. PMA-induced MCF-7 cell migration was reduced by 44, 79 and 90% following exposure to 25, 50 and 100 µM HDB, respectively, which was more markedly inhibited to 67, 79 and 92% following treatment with 25, 50 and 100 µM HMDB, respectively, compared with those treated with PMA only. To undergo invasion, cancer cells promote the degradation of the extracellular matrix in order to cross it (3). Therefore, the effect of DB, HDB or HMDB on PMA-induced MCF-7 cancer cell invasion was determined using an invasion chamber assay. The MCF-7 cells were seeded onto Matrigel-coated filters in the presence of DB, HDB or HMDB at 25, 50 and 100 µM and the number of cells, which invaded through the Matrigel were counted following incubation for 12 h. Treatments with DB, HDB and HMDB significantly inhibited PMA-induced cell invasion (Fig. 2). Treatment with 25, 50 and 100 µM DB reduced the cancer cell invasion by 1, 32 and 68%, respectively, compared with the PMA-only-treated cells. The PMA-induced MCF-7 cell invasion was reduced by 33, 81 and 90% following exposure to 25, 50 and 100 µM HDB, respectively, and was significantly inhibited to 57, 75 and 98% following treatment with 25, 50 and 100 µM of HMDB, respectively, compared with the PMA-only group. On the basis of these results, it was concluded that DB, HDB and HMDB inhibited the migration and invasion of the MCF-7 cells.

Figure 1. Effects of DB and its analogues, HDB and HMDB, on MCF-7 breast cancer cell migration. The MCF-7 cells were treated with various concentrations of DB, HDB and HMDB, followed by 10 ng/ml PMA for 12 h. Images of the migrating cells were captured using phase contrast microscopy (magnification, x100). The quantification data are expressed as the mean ± standard deviation of three independent experiments. *P<0.05, compared with the PMA only group. DB, dibenzoylmethane; HDB, hydroxdibenzoylmethane; HMDB, hydroxymethyldibenzoylmethane; PMA, phorbol-12-myristate 13-acetate; C, control.
Effects of DB, HDB and HMDB on the viability of the PMA-treated MCF-7 cells. To determine the cytotoxicity of DB and its analogues, HDB and HMDB, on the PMA-mediated MCF-7 cancer cells, the cells were treated with different concentrations (5, 10, 25, 50 and 100 µM) of DB, HDB or HMDB followed by the addition of PMA for 24 h. The cellular viability was then assessed using an MTT assay. The proportional viability (%) of the cells was determined by comparing each treated group with the PMA-only group, the viability of which was assumed to be 100% (Fig. 3). Treatment of the MCF-7 cells with DB, up to a maximal concentration of 100 µM, caused no significant change in cell viability. The cells had significantly lower viability following treatment with 100 µM HDB and 50 µM HMDB. Therefore, the antimetastatic effects of DB, HDB and HMDB were not associated with cell viability.

DB and its analogues inhibit the PMA-induced expression of MMP-9. The MMPs are a family of extracellular matrix degrading enzymes, which are associated with cancer cell metastasis. The type IV collagenases and gelatinases, MMP-9 and MMP-2, have been linked with high metastatic potential in breast carcinoma (20). Therefore, the effects of DB, HDB and HMDB on the enzyme activities and the gene expression levels of MMP-2 and MMP-9 were examined. The MCF-7 cells were treated with various concentrations of DB, HDB or HMDB followed by treatment with PMA in serum-free medium. The enzyme activities of the secreted MMP-2 and MMP-9 were assayed by gelatin zymography. As shown in Fig. 4A, DB, HDB and HMDB inhibited the enzyme activity of MMP-9, but not MMP-2, in a time-dependent manner. To determine whether DB, HDB and HMDB can inhibit the enzymatic activity of the secreted MMP-9 through the direct inhibition of these enzymes, various concentrations of DB, HDB and HMDB were incubated with conditioned medium derived from PMA-treated MCF-7 cells. The enzymatic activities of MMP-9 and MMP-2

Figure 2. Effects of DB, HDB and HMDB on MCF-7 breast cancer cell invasion. The MCF-7 cells were treated with various concentrations of DB, HDB and HMDB, followed by 10 ng/ml PMA for 12 h. The invasive ability was assessed using a Matrigel-coated in vitro invasion assay, as described (magnification, x200). The quantification data are expressed as the mean ± standard deviation of three independent experiments. *P<0.05, compared with the PMA only group. DB, dibenzoylmethane; HDB, hydroxydibenzoylmethane; HMDB, hydroxymethyldibenzoylmethane; PMA, phorbol-12-myristate 13-acetate; C, control.

Figure 3. Effects of DB, HDB and HMDB on MCF-7 breast cancer cell viability following PMA treatment. The MCF-7 cells were treated with various concentrations of DB, HDB and HMDB, followed by the addition of 10 ng/ml PMA for 24 h. The cell viability was assessed using an MTT assay. The quantification data are expressed as the mean ± standard deviation of three independent experiments. *P<0.05, compared with the PMA only group. DB, dibenzoylmethane; HDB, hydroxydibenzoylmethane; HMDB, hydroxymethyldibenzoylmethane; PMA, phorbol-12-myristate 13-acetate; MTT, 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide.
were assessed using gelatin zymography. As shown in Fig. 4B, MMP-9 and MMP-2 activity was detected in the conditioned media, and no significant differences were observed between the groups with or without treatment. Subsequently, to determine whether the inhibition of the enzymatic activities of MMP-9 and MMP-2 by DB, HDB or HMDB was due to a decreased level of mRNA transcription and protein synthesis, immunoblotting and RT-PCR were performed to examine the protein and mRNA expression levels of MMP-9 and MMP-2. As shown in Fig. 4C, DB, HDB and HMDB reduced the protein expression of the PMA-induced MMP-9, however no changes in the protein or mRNA expression of MMP-2 were observed. MMP-9 inhibitor I, a cell-permeable and reversible inhibitor of MMP-9, deceased the PMA-induced MCF-7 cell invasion (Fig. 4D). These results demonstrated that DB, HDB and HMDB disrupted the mRNA transcription and protein synthesis of MMP-9 in PMA-mediated metastasis.

Figure 4. DB, HDB and HMDB inhibit the PMA-induced expression of MMP-9 in MCF-7 cells. (A) MCF-7 cells were treated with 100 µM DB, 50 µM HDB and 25 µM HMDB, followed by the addition of 10 ng/ml PMA for 6, 12 and 24 h. The activity of the secreted MMP-9 and MMP-2 proteins was analyzed by gelatin zymography. (B) MMP-9 and MMP-2, derived from PMA-treated conditioned medium following stimulation for 24 h, was incubated with various concentrations of DB, HDB and HMDB for 30 min. The enzyme activities of MMP-2 and MMP-9 were analyzed using gelatin zymography. The light areas represent zones of lysis in gelatin gel were quantified by laser scanning densitometry. (C) MCF-7 cells were treated with DB, HDB and HMDB followed by the addition of 10 ng/ml PMA for 24 h. The protein and mRNA expression levels of MMP-9 and MMP-2 were analyzed using immunoblotting and reverse transcription polymerase chain reaction. (D) MCF-7 cells were treated with or without M9I-I and with PMA and then invasive ability was assessed using a Matrigel invasion assay (magnification, x200). The data are expressed as the mean ± standard deviation *P<0.05, compared with the PMA only group. DB, dibenzoylmethane; HDB, hydroxydibenzoylmethane; HMDB, hydroxymethyldibenzoylmethane; PMA, phorbol-12-myristate 13-acetate; M9I-I, MMP-9 inhibitor I; C, control.

PMA-induced activation of PKCδ and PI3K is reduced by DB, HDB and HMDB. The PKCδ and PI3K signaling pathways are important in cancer invasion (21,22). The present study aimed to determine the involvement of the activation of PKCδ and PI3K in the PMA-induced expression of MMP-9. The MCF-7 cells were treated with rottlerin (Rot), a PKCδ inhibitor or LY294002, a PI3K inhibitor, for 24 h, followed by the addition of PMA. As shown in Fig. 5A, Rot and LY effectively reduced the PMA-induced enzymatic activity and the mRNA expression of MMP-9 in a dose-dependent manner, as measured by gelatin zymography and RT-PCR, respectively. In addition, it was observed that the MCF-7 cells treated with 1 µM Rot and 10 µM LY reduced PMA-induced MCF-7 cell invasion (Fig. 5B). The activity of PKCδ was increased by the phosphorylation of Thr 505 and the activity of PI3K kinase was increased by the phosphorylation of Tyr458 in PI3K-p85 and of Tyr199 in PI3K-p55. Therefore, the
phosphorylation levels of PKCδ-Thr505, PI3K p85-Tyr458 and p55-Tyr199 were assessed by immunoblotting. As shown in Fig. 5C, the PMA-stimulated MCF-7 cells exhibited increased phosphorylation levels of PKCδ and PI3K. The increases in phosphorylated PKCδ and PI3K by PMA-stimulation were suppressed by treatment for 0.5, 1 and 3 h with 100 µM DB, 50 µM HDB and 25 µM HMDB. The order of potency of these compounds on the inhibition of PKCδ and PI3K phosphorylation were in the order HMDB>HDB>DB.

**Discussion**

The cause of mortality in the majority of patients with breast cancer is not from the primary cancer growth, but due to spread of the cancer cells to other parts of the body (23). Synthesized chemotherapeutic compounds demonstrate efficacy in treating metastatic breast cancer, however, certain chemotherapeutic agents possess toxic side effects (24). Therefore, the identification of naturally-derived antimetastatic, non-toxic, compounds is of particular interest. Natural products containing phenolic compounds have been widely reported to have the ability to prevent cancer metastasis (25). Flavonoids are a large subclass of phenolic compounds, prevalent in food and herbal nutraceuticals (26). DB, a β-diketone analogue of curcumin, belongs to the flavonoid family. Skin cancer frequently occurs at sun-exposed sites of the body, and sunscreen derivatives from DB have been used for protection against ultraviolet radiation (27). DB modulates the phase I/phase II detoxification
enzymatic systems (10,28) and with its analogues, HDB and HMDB, induces apoptosis in various types of cancer (15-18). However, their antimetastatic effects remain to be elucidated. The present study found that DB, HDB and HMDB significantly inhibited PMA-mediated MCF-7 cell migration and invasion (Figs. 1 and 2) and was the first, to the best of our knowledge, to demonstrate that DB, HDB and HMDB inhibit cancer cell migration and invasion.

MMPs are a family of Zn^{2+}- and Ca^{2+}-dependent endoproteases, comprising four subclasses (collagenases, gelatinases, stromelysins and membrane-type MMPs) based on their substrate (4). Increased levels of MMP-9 and MMP-2 are functionally associated with metastasis in several types of malignant tumor, including breast cancer (4,20). The present study indicated that DB, HDB and HMDB inhibited the expression of MMP-9, but not MMP-2, following PMA treatment (Fig. 4). MMP-2 is generally constitutively expressed in tissues and is maximally present in malignant neoplasms (29). By contrast, the expression of MMP-9 can be induced by various growth factors and inflammatory mediators during pathological states and by agents, including PMA (19,30).

PMA is a tumor promoter and an inflammatory stimulator, which increases the invasiveness of cancer cells, including breast cancer, by activating MMP-9 (19). DB is an effective inhibitor of PMA-induced mouse skin inflammation and tumor promotion (31). In the present study, the potency of inhibition by DB and its structural analogs on the expression of MMP-9 and their effects on the invasive potential of the PMA-treated MCF-7 cells was in the order HMDB>HDB>DB. Higher numbers of OH groups are present in flavonoid structures with increased anti-MMP activation (32,33). Compared with DB and HDB, HMDB has more marked anticancer effects in solid cancer cell lines (15).

PMA is a diacylglycerol mimic, which directly binds to and activates classical (α, β and γ) PKC isozymes (34). The activation of PKC involves the phosphorylation of PKC isoforms, causing cell proliferation, apoptosis, and cancer metastasis. The phosphorylation of PKCδ is involved in promoting cell invasion (35). PKCδ is an important signaling molecule for the expression of MMP-9 in cancer cell lines, including MCF-7 human breast carcinoma cells, CaSkii cells and HP-75 pituitary adenoma cells (32,36,37). The present study found that the DB analogues inhibited the phosphorylation of PKCδ in the MCF-7 cells following PMA treatment (Fig. 5C). PKCδ activates Ha-Ras-mediated signal transduction pathways (38) and human telomerase reverse transcriptase (hTERT) is phosphorylated by PKCδ (39). DB attenuates the expression of oncoproteins Ha-Ras and hTERT oncoproteins (40). The activation of MMP-9 is downstream of Ha-Ras (41) and knockdown of hTERT reduces the expression of MMP-9 in human glioblastoma cell lines (42). Inhibiting the activity of PKCδ by Rot enhances p38 mitogen activated protein kinase (MAPK) activation (43). HMDB activates p38 MAPK signaling (44), which suppresses the expression of MMP-9 in human stomach cancer (45). Nutraceuticals derived from spices, including curcumin, capsaicin and diosgenin, target the PI3K signaling pathway to regulate cancer metastasis (25) and activation of this pathway in breast cancer is associated with a poor prognosis (46). In the present study, DB, HDB and HMDB prevented the PMA-induced phosphorylation of PI3K in the MCF-7 cells (Fig. 5C). PI3Ks are heterodimeric serine/threonine kinases consisting of p110 catalytic and regulatory subunits and tyrosine phosphorylation of the p85 regulatory subunit reduces its inhibitory activity on PI3K (47). The PI3K inhibitor, LY294002, significantly diminishes the expression of phosphorylated PI3K-p85 (Tyr458)/p55 (Tyr459) (48). The results of the present and previous studies have revealed that the inhibition of PI3K activity can suppress the expression of MMP-9 and cancer cell invasion (21). These findings suggest that DB analogues inhibits PMA-induced metastasis by interfering with the PI3K/PI3Kδ-mediated expression of MMP-9.

In conclusion, the present study demonstrated that DB, HDB and HMDB exerted antimetastatic effects in PMA-treated MCF-7 breast cancer cells. The mechanism underlying this was the inhibition of the activity and expression of MMP-9 via the PKCδ and PI3K signaling pathways. Therefore, DB, HDB and HMDB may be potent chemopreventive agents in therapeutic strategies for metastatic cancers in the future.
