Abstract. Arsenic trioxide (As₂O₃) has been widely used in the treatment of acute promyelocytic leukemia and has been observed to exhibit therapeutic effects in various types of solid tumor. In a previous study by this group, it was shown that As₂O₃ induces the apoptosis of MCF-7 breast cancer cells through inhibition of the human ether-à-go-go-related gene (hERG) channel. The present study was designed to further investigate the effect of As₂O₃ on breast cancer cells and to examine the mechanism underlying the regulation of hERG expression. The present study confirmed that As₂O₃ inhibited tumor growth in vivo, following MCF-7 cell implantation into nude mice. Using computational prediction, it was identified that microRNA (miR)-328 had a binding site in the 3'-untranslated region of hERG mRNA. A luciferase activity assay demonstrated that hERG is a target gene of miR-328. Further investigation using western blot analysis and reverse transcription-quantitative polymerase chain reaction revealed that As₂O₃ downregulated hERG expression via upregulation of miR-328 expression in MCF-7 cells. In conclusion, As₂O₃ was observed to inhibit breast cancer cell growth, at least in part, through the miR-328/hERG pathway.

Introduction

Arsenic trioxide (As₂O₃) has been used medicinally for >2,400 years for conditions ranging from infectious diseases to cancer (1). It was not until 1970, that researchers at Harbin Medical University observed its ability to treat acute promyelocytic leukemia (2,3). As₂O₃ has also been demonstrated to exert inhibitory effects in various types of cancer. In MGC-803 human gastric cancer cells, As₂O₃ was shown to inhibit cell growth and to induce cell apoptosis (4). Similar findings were observed in esophageal carcinoma (5), neuroblastoma (6), prostate and ovarian carcinoma (7), and breast cancer (8) cells. Several mechanisms of action involved in the As₂O₃-induced apoptosis of cancer cells have been identified (8,9).

The human ether-à-go-go-related gene (hERG) is expressed in a number of tumor cell lines of various histogenetic origins, although is not present in the corresponding healthy cells, which indicates an association between hERG expression and the development of cancer (10-12). In a previous study by this group, it was identified that As₂O₃ induces the apoptosis of MCF-7 breast cancer cells via inhibition of hERG channels (13). To date, the molecular mechanisms underlying the regulation of hERG expression in breast cancer cells remain to be elucidated.

MicroRNAs (miRNAs/miRs) are a class of evolutionarily conserved, endogenous non-coding RNAs of ~22 nucleotides in length. They regulate gene expression at the post-transcriptional level by binding to the 3'-untranslated region (UTR) of the target mRNA. Altered expression of miRNAs has been demonstrated to be involved in cancer development and progression. To date, a number of downregulated miRNAs identified in breast cancer have also been shown to be associated with apoptosis (14,15) and metastasis (16,17).

Through computational prediction, it was shown that miR-328 may target the 3'-UTR of hERG mRNA. These findings prompted the hypothesis that As₂O₃ may inhibit breast cancer cell growth via the miR-328/hERG pathway. The present study was conducted to assess this hypothesis.

Materials and methods

Materials. As₂O₃ was obtained from Jiangsu Yida Chemical Co., Ltd. (Jiangyin, China) and was diluted with phosphate-buffered saline (PBS) to prepare a 10 mM stock solution, which was stored at 4°C in darkness.

Cell line and cell culture. The MCF-7 human breast cancer cell line was obtained from the American Type Culture Collection (Manassas, VA, USA). The cells were maintained in RPMI-1640 (HyClone, Logan, UT, USA) supplemented with
10% fetal bovine serum (Hyclone) in a humidified atmosphere with 5% CO$_2$ at 37°C.

**In vivo tumor xenograft model.** A total of 30 female BALB/c nude mice (nu/nu, 8 weeks old) were obtained from the Third Affiliated Hospital of Harbin Medical University (Harbin, China). The MCF-7 cells were inoculated subcutaneously into the flank of each mouse (5x10$^6$ cells in 200 µl PBS) (18). At 2 weeks following tumor implantation, the mice were randomly divided into three groups each containing 10 mice. The As$_2$O$_3$-treated groups were injected daily with 4 or 8 mg/kg of As$_2$O$_3$ for 7 days. The control group was administered with an equal volume of saline. Tumor size was measured using calipers and the volume was calculated according to the formula: $V = L \times W^2/2$, where $L$ and $W$ represent the length and width, respectively. The mice were weighed twice a week. Any investigations using the mice were performed in compliance with the guidelines of the Institute for Laboratory Animal Research, Mudangjiang Medical University.

**Luciferase assay.** The 3'-UTR of the hERG mRNA was obtained by polymerase chain reaction (PCR) amplification, and the PCR product was inserted into the firefly luciferase gene reporter construct (pMIR-REPORTTM; Ambion Life Technologies, Austin, TX, USA) as described previously (19). Mutation of the hERG sequence was created using a Quick Change Site-Directed Mutagenesis kit (Stratagene, Santa Clara, CA, USA). The miR-328 precursor (pre-miR-328) and a control precursor (scramble) were purchased from Ambion Life Technologies.

For the luciferase assay, HEK-293 cells were co-transfected with wild-type or mutant hERG 3'-UTR luciferase reporter plasmid, and pS-Neg or miR-328 expression plasmid, using Lipofectamine® 2000 (Invitrogen Life Technologies, Carlsbad, CA, USA). The luciferase activity was determined using a dual luciferase reporter assay system (Promega Corporation, Madison, WI, USA) at 48 h following transfection, according to the manufacturer's instructions.

**Reverse transcription-quantitative PCR (RT-qPCR).** Total RNA was extracted from MCF-7 cells using TRIzol® reagent (Invitrogen Life Technologies) according to the manufacturer's instructions. mir-328 levels were quantified using the mirVana qRT-PCR miRNA detection kit (Ambion Life Technologies), according to the manufacturer's instructions. Variations in the expression of mir-328 between different RNA samples were calculated following normalization to levels of U6.

**Western blot analysis.** Western blot analysis was conducted as described previously (20). The cells were washed with cold PBS and lysed in lysis buffer [western blot lysis: protease inhibitor cocktail (100:1); Beyotime Institute of Biotechnology, Haimen, China]. The concentration of proteins was determined using a bicinchoninic protein assay kit (Beyotime Institute of Biotechnology). The samples were electrophoresed using 10% SDS-PAGE. Following electrophoresis, the gels were transferred onto nitrocellulose membranes via electroblotting and blocked in 5% non-fat milk in PBS for 2 h. Subsequently, the membrane was incubated with polyclonal rabbit anti-hERG antibody (cat.no. sc-20130; 1:200 dilution; Santa Cruz Biotechnology, Inc., Santa Cruz, CA, USA) and polyclonal rabbit anti-GAPDH antibody (cat. no. sc-25778; 1:1,000 dilution; Santa Cruz Biotechnology, Inc.) in PBS and incubated at 4°C overnight. The following day, the membranes were washed three times with PBS for 5 min at room temperature and subsequently incubated with HRP-conjugated anti-rabbit IgG polyclonal secondary antibodies (1:10,000 dilution; cat. no. sc-2357, Santa Cruz Biotechnology, Inc.) for 2 h at room temperature. The Odyssey infrared fluorescence scanning system (LI-COR Biosciences, Lincoln, NE, USA) was used to detect protein bands. The intensity of the bands was determined by densitometry using Odyssey version 1.2 software (LI-COR Biosciences, Lincoln, NE, USA).

**Statistical analysis.** All data are presented as the mean ± standard deviation for three repeated experiments. Student's t-test and SPSS 16.0 (SPSS, Inc., Chicago, IL, USA) were used for statistical analysis. P<0.05 was considered to indicate a statistically significant difference.

**Results**

As$_2$O$_3$ inhibits tumor growth in MCF-7-inoculated nude mice. In order to examine the effect of As$_2$O$_3$ on breast cancer cells in vivo, human tumor xenografts were investigated in nude mice. The size of the tumor was measured, as shown in Fig. 1, in mice treated with 4 and 8 mg/kg, and As$_2$O$_3$-treated mice exhibited significant tumor growth retardation. The tumor volume of the non-treated mice increased between 1.19±0.31 and 3.18±0.67 cm$^3$, in comparison with mice treated with 4 mg/kg As$_2$O$_3$, which exhibited significant growth retardation, with tumor growth of between 0.74±0.30 and 0.97±0.57 cm$^3$. Notably, for the groups treated with 8 mg/kg As$_2$O$_3$, the tumor volume decreased between 1.44±0.55 and 1.02±0.42 cm$^3$. Regarding side effects of As$_2$O$_3$, no signs of toxicity were observed between the different groups, as judged at autopsy (data not shown). The present results indicated that As$_2$O$_3$ is effective in inhibiting tumor growth in MCF-7-inoculated nude mice.

As$_2$O$_3$ upregulates expression of miR-328 and downregulates expression of hERG. In order to further examine the mechanism underlying the regulation of hERG expression, the 3'-UTR of hERG was analyzed using the online databases, TargetScan Human version 6.2 (http://www.targetscan.org) and miRBase version 20.0 (http://www.mirbase.org), to identify potential interacting miRNAs. miR-133 and miR-328 were selected as likely interactors. Of the two selected miRNAs, miR-133 has been previously described as a muscle-specific miRNA, which has been investigated primarily with regard to the heart (21,22). Therefore, miR-328, a known tumor suppressor, was selected for further analysis.

Initially, the expression of miR-328 and hERG was detected in MCF-7 cells. The level of miR-328 was determined using RT-qPCR after MCF-7 cells had been treated with 8 µM As$_2$O$_3$ for 48 h. As shown in Fig. 2A, the expression of miR-328 in the treated cells increased by 56±0.34% compared with the level in non-treated cells. Subsequently, the level of hERG was determined using western blot analysis, following treatment of MCF-7 cells with 8 µM As$_2$O$_3$ for the same time.
As shown in Fig. 2B, the expression of hERG in the treated group decreased by 41±0.11% compared with that in the control group. It was therefore hypothesized that there is an inverse correlation between miR-328 and hERG protein expression levels.

It was hypothesized that miR-328 interacts directly with the 3'-UTR of hERG mRNA to suppress hERG expression. In order to assess this hypothesis, the ability of miR-328 to regulate the 3'-UTR of hERG was evaluated using luciferase reporter assays. The region from nucleotide +77 to nucleotide +83 of the hERG sequence (NM-001204798) was cloned downstream of a reporter luciferase gene (Fig. 3A).

HEK-293 cells were co-transfected with reporter plasmid and pre-miR-328/scramble miR. As a result, co-transfection of synthetic miR-328 and hERG-wildtype reduced the luciferase activity by ~46%, which was a significant difference compared with the scramble group. However, co-transfection of miR-328 in cells transfected with hERG-mutant did not significantly affect luciferase activity (Fig. 3B).

The most straightforward prediction from the luciferase reporter assay would be that ectopic expression of miR-328 should reduce hERG protein levels in MCF-7 cells. In order to further investigate the interaction between miR-328 and hERG, MCF-7 cells were transfected with pre-miR-328. Following pre-miR-328 transfection in MCF-7 cells (Fig. 3C), western blotting was conducted to measure the level of hERG protein. It was identified that the expression of hERG protein was downregulated by ~37% in pre-miR-328-treated MCF-7 cells. These data suggested that miR-328 directly recognizes the 3'-UTR of hERG mRNA and inhibits hERG translation.
Breast cancer is the most common type of cancer and is the leading cause of cancer-associated mortality in females, accounting for 25% of new cancer cases and 15% of the total global cancer-associated mortality in 2012 (23). Although important advances have been made in the early detection, prevention and treatment of breast cancer, chemotherapy remains the primary method of treatment, which leads to cumulative toxicity and has additional tolerability problems (24). An improved knowledge of tumor biology is providing the opportunity to treat breast cancer with a new class of anticancer drugs.

hERG is overexpressed in numerous types of cancer in humans, including endometrial cancer, leukemia, melanoma and neuroblastoma, and inhibition of the hERG channel may reduce cancer cell growth and proliferation (25-27). Furthermore, this group has recently demonstrated that As$_2$O$_3$ induces the apoptosis of MCF-7 cells through inhibition of the hERG channel (13). However, the mechanisms that regulate the expression of the hERG channel remain to be elucidated. Therefore, an objective of the present study was to identify potential miRNAs that are able to regulate hERG expression in human breast cancer cells.

The studies discussed thus far on miRNAs, reflect their ability to act as onco-miRNAs or oncosuppressor-miRNAs, by favoring or inhibiting tumor progression. In the present study, it was identified that in MCF-7 breast cancer cells, miR-328 is able to target the 3'UTR of hERG and to decrease its level of expression, thus suggesting that by maintaining hERG expression at a low level, the activity of miR-328 may contribute to tumor suppression.

In previous years, a number of miRNAs have been implicated in the development of human breast cancer. Iorio et al (28) first demonstrated miRNA dysregulation in human breast cancer. The authors found that miR-10b, miR-125b and miR-145 were downregulated, while miR-21 and miR-155 were upregulated, suggesting that they may act as potential tumor suppressor genes or oncogenes. Subsequently, additional functional studies were conducted in order to identify specific miRNAs involved in breast cancer. Wang et al (29) observed that miR-145 was downregulated in MCF-7 cells, and overexpression of miR-145 suppressed MCF-7 cell growth and induced apoptosis. Kong et al (30) demonstrated that miR-155 induces cell survival by targeting forkhead box O3a in breast cancer cells. Song et al (31) revealed that miR-21 negatively regulates TIMP metallopeptidase inhibitor 3 expression in breast cancer cells and promotes breast cancer invasion in multiple cell lines in vitro.

miR-328 expression in human cancer has not been extensively investigated thus far. Previously, miR-328 has been shown to be expressed in the small intestine and liver (32). Furthermore, it appears to be downregulated in high-grade gliomas (33) and a previous study demonstrated that it was also downregulated in the human colorectal cancer cell lines, HT29, HCT116 and HCT8 (32). In 5-Fluorouracil-treated MCF-7 cells, the expression of miR-328 increased in comparison with control cells (34). Similar results were observed in the present study, where miR-328 expression was upregulated in As$_2$O$_3$-treated MCF-7 cells.

Notably, miR-328 has been demonstrated to have dual actions in the regulation of cell functions, through base pairing with miRNA targets and via a decoy activity that interferes with the function of regulatory proteins (35). A
recent study demonstrated that miR-328 was able to target the 3′UTR of the breast cancer resistance protein, ATP-binding cassette sub-family G member 2 (ABCG2) and, consequently, repress ABCG2 protein expression and increase cancer cell sensitivity to drug treatment (36). miR-328 is also closely associated with cell cycle progression. It may increase proliferation of HeLa and SKBr3 cells, via down-regulation of protein tyrosine phosphatase, receptor type, J expression (37). Furthermore, ectopic miR-328 expression in glioblastoma cells may significantly suppress cell proliferation (33). Thus, the role of miR-328 in a appears to be dependent on the particular cell type involved.

The present data revealed that miR-328 expression is inversely correlated with hERG expression in MCF-7 breast cancer cells. However, the mechanisms underlying the regulation of miR-328 in human cancer remain to be elucidated and therefore require further investigation.

In conclusion, the results of the present study demonstrated a novel mechanism for the regulation of hERG expression by miR-328 in breast cancer cells, indicating that miR-328-hERG signaling mediated by As2O3 may represent a novel therapeutic target for breast cancer.
