Abstract. Aromatherapy has been suggested as an alternative therapeutic method for the treatment of atopic dermatitis (AD), eczema and other skin diseases. In the current study, the anti-atopic properties of the volatile organic compounds of *Chamaecyparis obtusa* (VOCCo) were examined to determine whether they are amenable for use as a pharmaceutical candidate. The alterations in histological features, serum IgE levels and mast cell infiltration following exposure to VOCCo were determined in a 2,4-dinitrochlorobenzene (DNCB)-induced AD-like mouse model. The results of these experiments demonstrated that VOCCo inhibited the development of AD-like skin lesions by reducing the serum IgE level and mast cell infiltration into the dermal and subcutaneous layers. This was supported by screening of immune cytokine mRNAs, including interleukin (IL)-1β and IL-6 from the skin of DNCB-treated mice. The expression of IL-1β and IL-6 in the skin lesions of mice was dose-dependently inhibited by treatment with VOCCo. Furthermore, treatment with VOCCo resulted in the recovery of histopathological features in AD-like skin lesions. These results suggest that VOCCo may have therapeutic and preventive effects for the development of AD.

Introduction

Atopic dermatitis (AD) has a complex etiology encompassing immunological responses, susceptibility genes, environmental triggers and compromised skin-barrier function (1). AD, also known as eczema, is a chronic inflammatory skin disease, which can occur in children and adults (2). AD is accompanied by symptoms of pruritus, erythema, edema and xerosis (3). The mechanisms underlying these skin diseases are also associated with genetic and environmental factors of AD pathogenesis (4). Immunoglobulin (Ig)E, which is important in the pathogenesis of allergy, is produced by B-lymphocytes following exposure of dendritic cells to a foreign antigen under the control of T-helper lymphocytes (5). An association between 70–85% of human AD and IgE hyper-production has been demonstrated and the extent of IgE sensitization is directly associated with the severity of the disease (6). When two or more molecules of IgE bound to the surface of an immune cell are simultaneously linked to its specific allergen, the immune cell immediately releases preformed inflammatory mediators, including histamine, which induces the immediate effects or early phase of an allergic reaction (1). Following IgE release, immune cells also synthesize newly formed inflammatory molecules, including cytokines, such as interleukins (IL) (1,7,8). The AD animal model, 2,4-dinitrochlorobenzene (DNCB)-induced contact hypersensitivity of the skin, is commonly used for investigating the pathogenesis of allergic contact dermatitis (9). DNCB, an allergen, can be internalized by local antigen presenting cells, including dermal dendritic cells and macrophages, processed and presented to T cells in the lymph nodes for activation (5), and cause AD-like symptoms, including eczema, erythema, scaling and hemorrhaging in skin lesions (1,6,8,10,11).

*Chamaecyparis obtusa* (C. obtusa), a species of cypress, is a tropical tree native to the central part of Japan and the southern part of Korea. Essential oil extracted from *C. obtusa* contains several types of terpenes, including monoterpenes, sesquiterpenes and diterpenes. The crude extract of *C. obtusa*...
reduces allergic reactions in an AD mouse model and effectively suppresses the levels of serum IgE and proinflammatory cytokines, as well as mast cell appearance under the dermis and hypodermis (12). *C. obtusa*, regarded as the most representative medicinal plant, contains active terpene compounds, which may have pharmacological effects (13). Volatile organic compounds (VOC) have been found to demonstrate an association with asthma and immune responses (14-16). To the best of our knowledge, there are no studies indicating that exposure to the volatile organic compounds of *C. obtusa* (VOCCo) can reduce allergic symptoms and, in particular, specific IgE responses and immune cell infiltration. In addition, the underlying mechanisms of the hypo-allergic effects of VOCCo have not yet been elucidated. The aim of the current study was to investigate whether VOCCo exposure is able to improve the symptoms of AD and to determine whether it is amenable for use as a pharmaceutical candidate.

**Materials and methods**

**Animals and induction of an AD mouse model.** BALB/c mice (7 weeks old) were purchased from Koatech (Pyeongtaek, Republic of Korea) and were housed in polycarbonate cages with *C. obtusa* panel and corn cob bedding and acclimated in an environmentally controlled room (temperature, 23±2°C; relative humidity, 50±10%; frequent ventilation and a 12:12-h light-dark cycle). The animal experiments were approved by the Chungbuk National University Animal Care and Use Committee (Cheongju, Korea) and all procedures were performed in accordance with the Guide for the Care and Use of Laboratory Animals published by the National Institutes of Health (Bethesda, MD, USA). DNCB (Sigma-Aldrich, St. Louis, MO, USA) dissolved in acetone:olive oil (4:1) was used for the induction of dermatitis in BALB/c mice. Briefly, hair was removed from a 2x4 cm region spanning from the neck to the pelvis and the dorsal skin was sensitized with 100 µl of 2% DNCB for 2 days during the first week. Following the first sensitization, 100 µl of 0.5% DNCB was applied three times a week to the dorsal skin for an additional 8 weeks. The VOCCo-untreated groups included the vehicle-treated (VE) group, DNCB treatment only group (DNBCB) and the Clobetasol propionate ointment group (DNBCB+CP). The VOCCo-treated groups included the DNBCB+P1 group (*C. obtusa* panel, 342 cm²), DNBCB+P2 group (684 cm²) and the DNBCB+P3 group (1,026 cm²). No substances were applied to the skin surface on the final day of the experiment. The mice were then sacrificed by ether inhalation and the skin, lymph nodes and blood samples were collected for further analysis.

**Level of serum IgE in an AD-like mouse model.** Blood samples were collected directly from the inferior vena cava using a capillary tube at the end of the experiment. Serum was obtained by centrifugation at 3,000 x g for 10 min at 4°C and stored at -70°C until use. Serum IgE levels were measured using a mouse IgE ELISA Ready-Set-Go kit (eBiosciences, San Diego, CA, USA) according to the manufacturer’s instructions.

**Histopathological alterations in an AD-like mouse model.** Dermis tissue was fixed by infiltrating the tissue with 10% formalin. The tissues were then embedded in paraffin, cut into sections (5 µm) and stained with hematoxylin and eosin (H&E). All tissue samples were examined and images were captured and scored in a blinded manner under a light microscope (BX51; Olympus, Tokyo, Japan). Images were captured on an Olympus DP controller and manager under a microscope at (BX51; Olympus) x100 magnification. For examination of the distribution of mast cells beneath the dermis and hypodermis, the prepared tissues were stained with toluidine blue and images were captured on an Olympus DP controller and manager under a microscope (BX51; Olympus) at x400 magnification. The number of mast cells in a 1 mm² area was counted under a microscope at x400 magnification.

**RNA extraction and quantitative polymerase chain reaction (PCR).** Total RNA was extracted from mouse skin using TRIzol reagent (Invitrogen Life Technologies, Carlsbad, CA, USA) according to the manufacturer’s instructions. RNA concentrations were measured using a microplate spectrophotometer (Epoch; BioTek Instruments Inc., Winooski, VT, USA) at 260 nm. RNA quality was evaluated by electrophoresis on 1% agarose gels. Total RNA (1 µg) was reverse transcribed into first-strand complementary DNA (cDNA) using Moloney murine leukemia virus reverse transcriptase (Invitrogen Life Technologies) and random primers (9-mer; Takara Bio, Inc., Otsu, Shiga, Japan). Each cDNA sample (1 µl) was amplified with 10 µl of 2X SYBR® Premix Ex Taq™ (Takara Bio, Inc.) and 10 pmol of each primer. Amplification was performed using a 7300 Real-time PCR System (Applied Biosystems, Foster City, CA, USA) with the following parameters: Denaturation at 95°C for 5 min followed by 40 cycles of denaturation at 95°C for 30 sec, annealing at 60°C for 30 sec and extension at 72°C for 45 sec. The following sequences of oligonucleotide primers were used in the present study: IL-1β, sense 5’-GAAATGCCACCTTTTGACAGTG-3’ and antisense 5’-CTGGATGCTCTCATCAGGACA-3’; IL-6, sense 5’-CTGCAAGAGACTTCCATCCAG-3’ and antisense 5’-AGTGATATAGACAGGTCTGGTG-3’; β-actin, sense 5’TCTTACATGAGCTGGTG-3’ and antisense 5’-ACCAGGACATACAGGGACA-3’. Relative expression levels in each sample (normalized to that of β-actin) were determined using RQ software (version 1.3; Applied Biosystems).

**Statistical analysis.** Data are presented as the mean ± standard error of the mean and were analyzed by one-way analysis of variance followed by Tukey’s multiple comparison test. Statistical analyses were performed using GraphPad Prism software (version 4.0; GraphPad Software Inc., La Jolla, CA, USA). P<0.05 was considered to indicate a statistically significant difference.

**Results**

**Effect of VOCCo on skin lesions and serum IgE levels in DNCB-treated mice.** For investigation of the anti-allergic effects of VOCCo in an AD-like mouse model, skin lesions were induced in BALB/c mice using multiple topical applications of DNCB for 8 weeks (Fig. 1). Marked inhibition of AD-like skin lesions was observed in the VOCCo (P1, P2 and P3) exposure groups. Treatment with DNCB resulted in induction of serum IgE levels (up to 7-fold) compared with...
the VE group. The elevated serum IgE level was decreased by clobetasol propionate (CP) treatment (Fig. 2). Exposure to VOCCo (P1, P2 and P3) resulted in a significant decrease in the elevated IgE level and this anti-allergic effect on serum IgE level was the highest in the P3 exposure group. The results indicated that exposure to VOCCo can reduce IgE levels in the serum, suggesting that VOCCo can ameliorate the hyper-allergic reaction in an AD-like mouse model.

**Histological findings in DNBC-treated mice.** For observation of skin thickness and immune cell infiltration, DNBC-affected skin lesions were collected and stained with H&E. As shown in Fig. 3, DNBC induced an increase in skin thickness in DNBC-treated mice, compared with the vehicle-treated group, and a decrease in VOCCo-exposed mice. VOCCo (1,026 cm$^3$) was expected to have greater potential for recovery of AD-like skin compared with the therapeutic control, CP. To determine the distribution of mast cells beneath the dermis and hypodermis of AD-like mice, selected tissues were stained with toluidine blue staining solution following formalin fixation (Fig. 3A). The number of mast cells was counted under a light microscope (BX51; Olympus) and expressed as the number of cells per square millimeter of dorsal skin (Fig. 3A). Infiltration of mast cells in DNBC-treated mice increased upon treatment with DNBC only, while infiltration was significantly decreased upon exposure in all VOCCo exposure groups (Fig. 3B). These findings suggest that VOCCo can inhibit the progression of AD-like skin lesions in the DNBC-induced AD mouse model.

**Effect of VOCCo on the expression of proinflammatory cytokines in AD-induced mice.** To determine the effect of VOCCo...
on the proinflammatory cytokines, IL-1β and IL-6, the transcriptional expression of these cytokines in DNCB-induced AD was evaluated. As shown in Fig. 4, the expression of IL-1β and IL-6 cytokines of the skin were induced by DNCB treatment. Elevated expression of dermal IL-1β and IL-6 mRNA was attenuated by CP treatment in AD-induced mice. Expression of IL-6 mRNA demonstrated a decrease in all VOCCo groups (P1, P2 and P3) compared with the DNCB only treatment group. In addition, dermal IL-1β mRNA expression decreased. These results suggest that VOCCo can inhibit proinflammatory gene expression in the skin, which may be important in the suppression of allergic reactions in an AD mouse model.
understanding normal and pathological immune responses in Th1/Th2 subsets in Th lymphocytes provides a framework for and to ameliorate allergic symptoms (19,20). The existence of treatment is expected to prevent the onset of allergic diseases an alternative method for anti-AD treatment and this type of Use of compounds from plants has previously been reported as are prescribed for a short course in an effort to calm the rash. body (11,18). To avoid these side effects, certain medications side effects and drug tolerance in the endocrine system of the corticosteroids is associated with a significant number of of AD (17,18). However, long term use of oral and topical ointments are also available for the control of AD -symptoms can be used for the treatment of AD (1). Corticosteroids may be used for monotherapy treatment of AD when conventional treatments, including corticosteroids are unsuccessful, however, the medicine was ineffective for the treatment of AD. Previously, new topical calcineurin inhibitors, including tacrolimus ointment and pimecrolimus cream, have been used for monotherapy treatment of AD when conventional treatments, including corticosteroids are unsuccessful. Although the mechanisms of herbal remedies have not yet been fully elucidated, a number of remedies may have scientific merit and clinical benefit for patients (12,13,19,27,28). In conclusion, the present study demonstrated the anti-allergic effects of VOCCo in a DNCB-induced AD mouse model. The induced serum IgE level was significantly decreased by application of VOCCo in DNCB-induced AD mice. In addition, this treatment resulted in the recovery of histological features. Exposure to VOCCo was demonstrated to result in successful elimination of the AD symptoms of skin lesions and mast cell infiltration beneath the hypodermis was also effectively inhibited. Cytokine mRNAs (IL-1β and IL-6) from skin lesions of DNCB-treated mice were significantly inhibited, suggesting that VOCCo may contribute to suppression of the stimulation of T cell-mediated cytokines in DNCB-induced mice.

Over the last half century, topical corticosteroids have been the primary choice for the treatment of AD. However, conditions, including skin atrophy, striae and perioral dermatitis, in sensitive areas (face or skin folds) have prevented the long-term use of corticosteroids for the treatment of AD (26). Previously, new topical calcineurin inhibitors, including tacrolimus ointment and pimecrolimus cream, have been used for monotherapy treatment of AD when conventional treatments, including corticosteroids are unsuccessful, however, the medicine was ineffective for the treatment of AD. Numerous patients stop seeking help from conventional physicians and turn to alternative medical approaches (27); these can include natural products. Although the mechanisms of herbal remedies have not yet been fully elucidated, a number of remedies may have scientific merit and clinical benefit for patients (12,13,19,27,28).

In conclusion, the present study demonstrated the anti-allergic effects of VOCCo in an AD mouse model. Based on the results of the present study, it appears that VOCCo may be a potential therapeutic compound for the treatment of AD, and control of the levels of serum IgE and T cell-derived cytokines, IL-1β and IL-6 in skin lesions of an AD mouse model.
