Abstract. Progress in the last decade has improved the treatment of acute myeloid leukemia (AML); however, the treatment of AML is also demanding and better treatments are required. The present study aimed to examine the antiproliferative and proapoptotic effects of macrocalyxin A (MA), a novel deterpenid compound, on AML cells. It was identified that MA significantly inhibits kasumi-1 cell proliferation in a time- and dose-dependent manner. Furthermore, low concentrations of MA were able to induce kasumi-1 cell differentiation; however, high concentrations of MA induced kasumi-1 cell apoptosis. MA was also able to increase the expression of mitochondrial membrane protein in a dose-dependent manner while the ΔΨm was reduced. Additionally, Bad expression in kasumi-1 cells was increased when treated with MA, indicating that the intrinsic apoptotic pathway may be important in MA-induced kasumi-1 cell apoptosis, where the mitochondrial permeability transition pore is opened and the ΔΨm is reduced. In addition, it was demonstrated that AML-ETO mRNA may also be important in MA-induced apoptosis.

Introduction

Acute myeloid leukemia (AML) is a clonal disease characterized by the proliferation and accumulation of myeloid progenitor cells in the bone marrow, which ultimately leads to hematopoietic failure (1). Chromosome translocations are frequently present in AML and are important in leukemia development (2). Furthermore, 5-10% of all patients with AML have the t (8;21) abnormality, which can generate the AML-ETO fusion oncoprotein blocking myeloid cell differentiation and apoptosis (3-5). The prognosis of elderly patients with AML is poor, with a median survival of 4-7 months despite intensive chemotherapy (6), and the 5-year survival ratio of patients with AML that are <60-years old is only 30-45% (7,8). Despite the fact that there have been several practice-changing developments in the diagnosis and treatment of AML, chemotherapy remains one of the most extensively used methods. However, increased tumor cell resistance and the increased drug toxicity provides problems with current chemotherapeutic agents for AML (9,10). Therefore, identification and development of novel drugs remains important.

Chinese herbal medicines, which have been widely found to inhibit proliferation, induce apoptosis, suppress angiogenesis, retard metastasis and enhance chemotherapy, exhibit anticancer potential in vitro and in vivo (11-15). For example, β-elemene, a compound isolated from Curcuma, exerts anticancer potential and is used as an innovative drug treatment (12). Additionally, oridonin was also a diterpenoid isolated from the isodon plant Rabdosia rubescens (HemsI.) Hara (Donglingcao), which demonstrated anticancer activity in different tumors, such as Ehrlich ascites carcinoma, sarcoma-180 solid tumor or t (8;21) AML cells (16).

Macrolcalyxin A (MA), a deterpenid compound (Fig. 1), was purified from the other isodon plant Rabdosia macrocalyx (Dunn) Hara, which is widely used in jaundice and acute hepatitis, acute cholecystitis and other inflammatory diseases in Chinese medicine. In the present study, using this novel deterpenid compound, it was demonstrated that MA can reduce the viability and enhance apoptosis in AML cells, which may ascribe to the induction of apoptosis by upregulation of Bad, and open the mitochondrial permeability transition pore and reduce ΔΨm. Furthermore, AML-ETO mRNA may also be important in MA-induced apoptosis. In conclusion, the synthesis of a novel drug that, by virtue of its initial assessments, promises to be an effective anticancer agent against AML.

Materials and methods

MA. MA with a purity of ≥99% was provided by Mrs. Ya-Ping Lv (Zhejiang Technology University, Hangzhou, China; Fig. 1), a stock solution was dissolved in dimethyl sulfoxide (DMSO; Sigma Aldrich, Carlsbad, CA, USA) at 5 mg/ml and stored
at -80°C. Then MA was added to the cell culture medium at the different concentrations (0, 4, 8, 12 and 16 µg/ml).

Cell culture and morphology observation. The following human cell lines (obtained from Zhejiang University, Hangzhou, China) were used: kasumi-1 AML leukemia cells with t (8;21) translocation, and NB4 and HL60 acute promyelocytic leukemia cells. These cells were cultured at 37°C with 5% CO₂ in RPMI-1640 medium (Gibco-BRL, Carlsbad, CA, USA) and supplemented with 10% heat-inactivated fetal calf serum (Gibco-BRL). Cell viability was detected by propidium iodide (PI; Bender Medsystems, Vienna, Austria) staining with flow cytometry. For morphological observation, cells were observed under light microscopy with Wright's staining (Solarbio, Shanghai, China) and Hoechst 33258 fluorescence staining (Sigma-Aldrich). To evaluate the apoptotic activity of kasumi-1 cells, Hoechst-33258 and Wright's staining were used to observe changes in the cell nucleus. The kasumi-1 cells (5x10⁶ cells in 2 ml) were seeded in 6-well plates overnight and exposed to increasing concentrations of MA for 24 and 48 h. The cells for Hoechst-33258 staining were fixed with methanol/glacial acetic acid (3:1) for 5 min at 4°C and incubated with Hoechst-33258 (5 µg/ml) for 15 min after washing with phosphate-buffered saline (PBS). Then the cells were observed under a fluorescence microscope (Nikon Y-THS, Nikon, Tokyo, Japan). The cells for Wright's staining were stained with Wright A and B staining (Solarbio) for 10 min and observed under a light microscope (Olympus CHA; Olympus, Tokyo, Japan).

Cell proliferation assay. Briefly, cells were seeded into 96-well plates at 30,000-40,000 cells/well and treated with MA (4-16 µg/ml) for 24 and 48 h. Subsequently, the cells were incubated at the different time points with 10 µl 3-[4,5-dimethylthiazol-2-yl]-2,5-diphenyltetrazolium bromide (MTT; 10 mg/ml; Sigma-Aldrich) at 37°C for 4 h. After the medium was aspirated, the formazan crystals were dissolved in 150 µl DMSO (Sigma-Aldrich). In brief, the mixture was incubated for 15 min in the dark at room temperature and detected by flow cytometry. For morphological observation, cells were stained with Annexin V binding buffer at a final concentration of 1X Annexin V binding buffer (Bender Medsystems). In brief, cells were resuspended in Annexin V binding buffer at a final concentration of 1x10⁶ cells/ml. Subsequently, 5 µl fluorescein isothiocyanate (FITC)-Annexin V and 10 µl PI were added to a 100 µl cell suspension with a cell concentration of 1x10⁶ cells/ml. The mixture was incubated for 15 min in the dark at room temperature and detected by flow cytometry. The mitochondrial ∆Ψm was also determined using flow cytometry. Briefly, kasumi-1 cells were treated with different concentrations (4, 8, 12 and 16 µg/ml) of MA for 24 h, then washed with PBS, ~2x10⁶ cells were incubated with 10 µg/ml rhodamine 123 (RH123, Sigma-Aldrich) at 37°C for 30 min. Then the cells were washed with PBS and stained with 50 µg/ml PI. The fluorescence intensity was measured by flow cytometry.

Flow cytometric assays for annexin-V/PI and mitochondrial transmembrane potentials. To assess the early apoptosis of treated cells, an Annexin-V assay was performed on a Navios flow cytometer (Beckman Coulter, Miami, FL, USA) according to instructions provided in the Annexin-V kits (Bender Medsystems). In brief, cells were resuspended in 1X Annexin V binding buffer at a final concentration of 1x10⁶ cells/ml. Subsequently, 5 µl fluorescein isothiocyanate (FITC)-Annexin V and 10 µl PI were added to a 100 µl cell suspension with a cell concentration of 1x10⁶ cells/ml. The mixture was incubated for 15 min in the dark at room temperature and detected by flow cytometry. The mitochondrial ∆Ψm was also determined using flow cytometry. Briefly, kasumi-1 cells were treated with different concentrations (4, 8, 12 and 16 µg/ml) of MA for 24 h, then washed with PBS, ~2x10⁶ cells were incubated with 10 µg/ml rhodamine 123 (RH123, Sigma-Aldrich) at 37°C for 30 min. Then the cells were washed with PBS and stained with 50 µg/ml PI. The fluorescence intensity was measured by flow cytometry.

Flow cytometric assays for nuclear DNA content distribution. For the distribution of nuclear DNA content, cells treated with MA were harvested, rinsed and washed in PBS, then cells were treated under instructions of the DNA-Prep kit (Beckman Coulter, Miami, FL, USA) and flow cytometry was conducted. All the data were collected and analyzed by muticycle software version 6-16-03-F32 (Beckman Coulter).

Reverse transcription-quantitative polymerase chain reaction (RT-qPCR) analysis. RT-qPCR was performed to measure the expression of AML-ETO. Briefly, total RNA was extracted from cells with TRIzol reagent (Invitrogen Life Technologies, Carlsbad, CA, USA) under the manufacturer's instructions. Then 1 µg total RNA was reverse-transcribed using Invitrogen Superscript II reverse transcriptase (Invitrogen Life Technologies, Waltham, MA, USA) and the first strand complementary DNA synthesis was performed using SuperScript II RT (Invitrogen Life Technologies). Then the qPCR was performed using the SYBR Green PCR master mix (Takara Bio Inc., Otsu, Japan) in the 7500 ABI Prism (Applied Biosystems, Foster City, CA, USA), and the reaction conditions were as follows: 50°C for 2 min, 95°C for 10 min, then 40 cycles of 95°C for 15 sec followed by 60°C for 1 min. The melt analysis was performed by increasing the temperature from 65-95°C. The AML-ETO gene was normalized to the expression of the housekeeping gene β-actin. The primer sequences were as follows: AML-ETO, forward 5'-GTCTTCACAAACCCA CGCAAG-3', and reverse 5'-GTCAAGGCTGATTGGCT TTC-3'; β-actin, forward 5'-AAGGAGCCCAACGAGAAA AAT-3', and reverse 5'-ACCGAAGCTTGATGGATCC-3'. The relative amount of AML-ETO mRNA level was calculated as the average 2-ΔCt where ΔCt = Ct – Ct β-actin.

Western blot analysis. In order to determine the potential mechanism underlying the effects of MA on kasumi-1 cell activity, protein expression of relative genes was measured by western blot analysis. Briefly, cells were harvested, washed and lysed with lysis buffer (62.5 mM Tris-HCl, pH 6.8; 2% SDS, 100 mM DT and 10% glycerol), cell lysates were centrifuged at 25,000 x g for 15 min at 4°C, then proteins in the
supernatant were quantified by the bicinchoninic acid method according to the manufacturer’s instructions (Pierce, Rockford, IL, USA), protein lysates (20 µg) were resolved on a 10-15% SDS-polyacrylamide gel electrophoresis, and transferred to a polyvinylidene difluoride membrane (Whatman, Maidstone, UK), the following antibodies were used: Rabbit monoclonal antibody (mAb) pro-caspase-3 (1:1,000; cat. no. 9665), rabbit polyclonal antibody (pAb) Bax (1:1,000; cat. no. 2774), NF-κB

Figure 2. MA inhibits cell proliferation in leukemia cells. (A) Kasumi-1 cells were cultured with MA (4-16 µg/ml), after 24 h cell viability was observed by PI staining and flow cytometry. (B) Kasumi-1 cells cultured with MA (4-16 µg/ml), after 48 h, cell viability was determined by PI staining by flow cytometry. (C) Kasumi-1 cells cultured with MA (4-16 µg/ml), after 24 h and 48 h, MA significantly inhibited the proliferation of kasumi-1 cells, and the cell viability were time and dose dependent. (D) IC₅₀ obtained from MTT assay in kasumi-1, HL-60 and NB4 cells treated with MA for 24 h respectively. MA, macrocalyxin A; PI, propidium iodide.

Figure 3. Morphological observation of MA treatment in kasumi-1 cells. (A) Wright’s staining for the control kasumi-1 cells without MA treatment (magnification, x1,000). (B) Hoechst-33258 fluorescence staining for the control kasumi-1 cells without MA treatment (magnification, x200). (C) Wright’s staining for the Kasumi-1 cells treated with 4 µg/ml MA for 24 h (magnification, x1,000). In certain apoptotic cells, a shrinking cytoplasm, condensed chromatin and nuclear fragmentation were observed. (D) Hoechst-33258 fluorescence staining for the Kasumi-1 cells treated with 4 µg/ml MA for 24 h (magnification, x200). MA, macrocalyxin A.
rabbit pAb (1:1,000; cat. no. 3034), rabbit mAb Bad (1:1,000; cat. no. 9239), rabbit pAb ETO (1:1,000; cat. no. 4498), which were all purchased from Cell Signaling Technology (Danvers, MA, USA). The mouse mAb Bcl-2 (1:250; cat. no. sc-7382), mouse mAb β-actin (1:1,000; cat. no. sc-47778), which were purchased from Santa Cruz Biotechnology, Inc. (Santa Cruz, CA, USA). Additionally, corresponding horseradish peroxidase-conjugated secondary antibodies were purchased from the Cell Signaling Technology. The band intensities were measured using densitometry by means of the quantity one version software (Bio-Rad, Hercules, CA, USA).

Statistical analysis. Quantitative data are presented as the mean ± standard deviation. Statistical significance was determined by means of the two-tailed Student's t-test. Statistical analysis was performed using SPSS 15.0 (SPSS, Inc., Chicago, IL, USA). All results were obtained from three separate experiments. P<0.05, 0.01 and 0.001 were considered to indicate a statistically significant difference.

Results

MA suppresses AML cell proliferation. To evaluate the effect of MA on the viability of AML cells, three AML cell lines (NB4, HL-60 and kasumi-1) were treated with MA at different concentrations (4, 8, 12 and 16 µg/ml) and their viability was detected by an MTT assay. The MTT assay showed that MA inhibited the proliferation of the three cell lines in a dose-dependent manner at different time points, and the half maximal inhibitory concentration (IC₅₀) was measured in those cells with MA at concentrations of 5-9 µg/ml for 24 h, respectively, where the IC₅₀ values were 6.5, 8.34 and 8.76 µg/ml in the kasumi-1, NB4 and HL-60 cells, respectively (Fig. 2A). Additionally, it was observed that MA significantly inhibited the proliferation of kasumi-1 cells, and this effect occurred in a time- and dose-dependent manner (Fig. 2B), and the average growth inhibition percentages were 25, 58, 76 and 92% following treatment with 4, 8, 12 and 16 µg/ml MA, respectively, for 24 h (Fig. 2C). Thus, following 48 h of
MA (MA), a deterpenid, were used in the apoptosis effect of MA, the effects of MA on cells. In order to understand the underlying mechanism of apoptosis, and RH123 was first used to measure the mitochondrial pathway is an important intrinsic pathway in collapse of MA-induced apoptosis is associated with caspase-3 and that MA could induce the apoptosis of kasumi-1 cells.

To confirm whether the growth inhibition of kasumi-1 cells was caused by apoptosis, kasumi-1 cells with MA treatment were observed under a microscope, when the kasumi-1 cells were treated with MA, the appearance of morphological characteristics of apoptosis, such as shrinking cytoplasm, condensed chromatin and nuclear fragmentation was observed (Fig. 3). Additionally, the Annexin V-FITC/PI double-staining kit was used to detect the effect of MA on apoptosis. It was found that following treatment with MA at different concentrations for 12 h, the early apoptosis rates of kasumi-1 cells synchronized with MA concentrations, reaching 0.3, 8.4, 15.7, 28.4, 33.2% at concentrations of 0, 4, 8, 12 and 16 μg/ml (Table I). Thus, the apoptosis effect with MA in kasumi-1 cells occurred in a dose-dependent manner. Additionally, the cell cycle of kasumi-1 cells was also detected with MA at 4, 8, 12, 16 μg/ml for 24 h. No significant change was identified in the G1, S and G2/M proportion in kasumi-1 cells treated with MA; however, the sub-G1 cells were increased in a dose-dependent manner (Fig. 4, Table I). These results indicated that MA could induce the apoptosis of kasumi-1 cells.

**MA induces the apoptosis of kasumi-1 cells.** To confirm whether the growth inhibition of kasumi-1 cells was caused by apoptosis, kasumi-1 cells with MA treatment were observed under a microscope, when the kasumi-1 cells were treated with MA, the appearance of morphological characteristics of apoptosis, such as shrinking cytoplasm, condensed chromatin and nuclear fragmentation was observed (Fig. 3). Additionally, the Annexin V-FITC/PI double-staining kit was used to detect the effect of MA on apoptosis. It was found that following treatment with MA at different concentrations for 12 h, the early apoptosis rates of kasumi-1 cells synchronized with MA concentrations, reaching 0.3, 8.4, 15.7, 28.4, 33.2% at concentrations of 0, 4, 8, 12 and 16 μg/ml (Table I). Thus, the apoptosis effect with MA in kasumi-1 cells occurred in a dose-dependent manner. Additionally, the cell cycle of kasumi-1 cells was also detected with MA at 4, 8, 12, 16 μg/ml for 24 h. No significant change was identified in the G1, S and G2/M proportion in kasumi-1 cells treated with MA; however, the sub-G1 cells were increased in a dose-dependent manner (Fig. 4, Table I). These results indicated that MA could induce the apoptosis of kasumi-1 cells.

**MA-induced apoptosis is associated with caspase-3 and collapse of ∆ψm through upregulation of bad/bcl-2.** The mitochondria pathway is an important intrinsic pathway in apoptosis, and RH123 was first used to measure the ∆ψm in cells. In order to understand the underlying mechanism in the apoptosis effect of MA, the effects of MA on ∆ψm were evaluated with RH123 staining. The results showed that untreated living cells were strongly stained by RH123 when exposed to MA at 4, 8, 12, 16 μg/ml, the mean fluorescence intensity of RH123 in kasumi-1 cells was significantly decreased, suggesting that the cell membrane potential was decreased in a dose-dependent manner (Fig. 5A). Furthermore, to identify whether MA damaged mitochondria via bcl-2, bad, bax proteins, their expression levels were investigated in kasumi-1 cells when incubated with MA for 24 h at 4 μg/ml concentration. The results of western blot showed that the protein expression of Bad was increased in a dose-dependent manner, whereas no significant change in the expression of bcl-2 and bax was observed. Additionally, in parallel to ∆ψm, procaspase-3 was decreased. These results suggested that MA induced cell apoptosis through the caspase-dependent mitochondrial pathway (Fig. 5B).

**Figure 6. Effects of MA on AML-ETO fusion gene and protein.** (A) MA inhibits expression of AML-ETO mRNA in kasumi-1 cells compared with control cells. (B) Effect of MA on the protein expression of ETO. Lane 1, treatment with 0 μg/ml MA; lane 2, treatment with 4 μg/ml MA; and lane 3, treatment with 8 μg/ml MA. MA causes a degradation of AML-ETO protein in MA-treated kasumi-1 cells. MA, macrocalyxin A.

**MA induces degradation of AML-ETO oncoprotein in association with blockade of AML-ETO mRNA.** AML1-ETO, which is generated by the chromosomal translocation t (8; 21) (q22; q22), has been shown to lead to the abnormal proliferation of leukemic cells, and the arrest of cell division and differentiation. To identify whether MA affects the AML cells through this target, RT-qPCR analysis for expression of AML-ETO mRNA was conducted. It showed that the expression levels of AML-ETO were significant lower in the kasumi-1 cells with MA treatment than in untreated cells (Fig. 6A). Furthermore, to further verify this MA-mediated AML-ETO degradation, anti-ETO antibodies were used in western blots. It was found that MA degraded the AML-ETO protein in kasumi-1 cells when treated with MA for 24 h at 4, 8 μg/ml (Fig. 6B).

**Discussion**

In recent years, it has been reported that a number of natural products isolated from Chinese herbs have been found to inhibit proliferation, induce apoptosis, suppress angiogenesis, retard metastasis and enhance chemotherapy, exhibiting anticancer potential in vitro and in vivo. MA (MA), a deterpenid compound purified from Rabdosia macrocalyx (Dunn) Hara, was widely used in jaundice and acute hepatitis, acute cholecystitis and other inflammatory diseases in Chinese medicine. In this study, the results of the MTT assay demonstrated that MA can inhibit the proliferation of kasumi-1 cells in a dose- and time-dependent manner. Moreover, results of Annexin V/PI staining, nuclear DNA content distribution, DNA gel electrophoresis and morphology analysis suggested that MA can induce apoptosis of kasumi-1 cells.

The extrinsic and intrinsic apoptotic pathways are two classic cell apoptosis routes. The mitochondrial membrane exhibits an important role in the intrinsic pathway and disruption of the intrinsic pathway is common in cancer cells. During apoptosis, the permeability of the mitochondrial membrane increases, leading to the loss of membrane potential and release of cytochrome c in the cytosol. Released cytochrome c binds to Apaf-1, which activates caspase-9, triggering caspase-3 activation and resulting in the cleavage of PARP. The mitochondrial death pathway is controlled by members of the Bcl-2 family, which exhibit a central regulatory role to
decide the fate of the cells via interactions between pro- and anti-apoptotic members (19,20). During apoptosis, Bcl-2 family pro-apoptotic proteins can translocate to the outer membrane of mitochondria, promote the release of pro-apoptotic factors and induce apoptosis. Conversely, Bcl-2 family anti-apoptotic proteins sequester in the mitochondria inhibiting the release of pro-apoptotic factors and preventing apoptosis. After receiving apoptosis signals, whether or not the cells can survive depends on the ratio of anti-apoptotic/pro-apoptotic Bcl-2 family. The cell dies if the Bad family is dominant, and survives when Bcl-2 is dominant (17,21). In the present study, the results of western blot analysis showed that cells treated with MA increased the level of the pro-apoptotic protein Bad, while the level of the anti-apoptotic protein Bcl-2 was markedly changed. Furthermore, a marked attenuation of ΔΨm occurred in cells exposed to MA in a concentration-dependent manner. In addition, it was also observed that MA increased the caspase-3 activity. These results showed that the apoptosis effect of MA in kasumi-1 cells was dependent on the mitochondrial pathway.

The AML-ETO fusion gene is the most frequently mutated gene in AML, and ~46% of patients with AML exhibit French-Americal-British (FAB)-M2 morphology (22). The AE fusion protein inhibits transcription of AML1 target genes, activates transcription of apoptotic antagonist Bcl-2, enhances self-renewal of hematopoietic stem/progenitor cells, blocks hematopoietic differentiation and disturbs normal cell proliferation (22,23). Additionally, it has been reported that treatment strategies interfering with AE oncoprotein in leukemia showed high therapeutic efficacy with low adverse effects. Oridonin, a diterpenoid isolated from the isodon plant, targeted the AML-ETO fusion protein with few adverse effects in patients with t (8;21) leukemia in vitro and in vivo (16). Eriocalyxin B induces apoptosis of leukemia cells and triggers degradation of AML-ETO in a caspase-3-dependent manner (23). In the present study, the mRNA expression level of AML-ETO and the AML-ETO fusion protein were analyzed. RT-qPCR showed that AML-ETO mRNA levels decreased in a dose-dependent manner, and the fusion protein was also degraded following treatment with MA. To an extent, it was determined that MA affects the biology of AML cells through the AML-ETO target.

In conclusion, the results showed that MA can inhibit kasumi-1 cell proliferation and induce apoptosis. The underlying mechanism may be associated with the intrinsic apoptosis pathway via its upregulation of Bad, which opens the mitochondrial permeability transition pore and reduces ΔΨm. Furthermore, AML-ETO mRNA may also be involved in MA-induced apoptosis.
