Abstract. Malignant gliomas, which comprise the most common type of primary malignant brain tumor, are associated with a poor prognosis and quality of life. Paclitaxel (Taxol) and temozolomide (TMZ) are Food and Drug Administration-approved anticancer agents, which are known to have therapeutic applications in various malignancies. However, similar to other chemotherapeutic agents, the development of resistance to TMZ and Taxol is common. The aim of the present study was to investigate the regulation of glucose metabolism by TMZ and Taxol in glioma cells. The results demonstrated that glioma cells exhibit decreased glucose uptake and lactate production in response to treatment with TMZ; however, glucose metabolism was increased in response to Taxol treatment. Following analysis of TMZ- and Taxol-resistant cell lines, it was reported that glucose metabolism was decreased in the TMZ-resistant cells, but was increased in the Taxol-resistant cells. Notably, a combination of TMZ and Taxol exerted synergistic inhibitory effects on Taxol-resistant glioma cells. However, the synergistic phenotype was not observed following treatment with a combination of 5-fluorouracil and Taxol. Furthermore, restoration of glucose metabolism by overexpression of glucose transporter 1 in Taxol-resistant cells resulted in regained resistance to Taxol. Therefore, the present study proposes a novel mechanism accounting for the synergistic effects of Taxol and TMZ co-treatment, which may contribute to the development of therapeutic strategies for overcoming chemoresistance in patients with cancer.

Introduction

Gliomas are primary malignant brain tumors that exhibit aggressive properties and are associated with a poor prognosis in adults (1,2). Glioma cells are able to invade healthy brain tissue and possess enhanced resistance to radiotherapy- and chemotherapy-induced apoptosis (3). Temozolomide (TMZ) comprises an orally bioavailable alkylating agent, which targets nuclear DNA and generates nuclear DNA adducts that block the cell cycle leading to apoptotic cell death (4). Currently, adjuvant chemotherapy with TMZ is the standard treatment for patients exhibiting primary glioblastoma multiforme (GBM) (5,6). The chemotherapeutic regimen is commonly administered as part of the treatment for GBM; however, the majority of patients eventually develop resistance to chemotherapy (7,8). Therefore, understanding the underlying mechanisms that determine tumor response to TMZ is considered to be crucial.

The Warburg effect is defined as the increased utilization of glucose, which is produced by glycolysis (9). Normal tissue relies primarily on mitochondrial oxidative phosphorylation to generate the energy required for cellular processes; however, the majority of cancer cells switch to aerobic glycolysis. This difference suggests that targeting metabolic dependence may be a selective approach for the treatment of clinical patients. Therefore, glycolytic inhibition has been applied as an anticancer strategy in the context of selected components of the glycolytic pathway, including glucose transporters (Gluts), hexokinase, pyruvate kinase M2 and lactate dehydrogenase-A (LDHA) (10). It has previously been reported that LDHA expression and activity are higher in Taxol-resistant breast cancer cells, versus those in parental cells, and down-regulation of LDHA resensitized Taxol-resistant cells (11) indicating that dysregulated cellular metabolism may be a therapeutic target for overcoming drug resistance in cancer therapy.

The aim of the present study was to investigate the glucose metabolism of glioma cells in response to treatment with TMZ. The results demonstrated that glioma cells exhibited decreased glucose uptake and lactate production.
Materials and methods

Cell culture and antibodies. The U251 and LN229 human glioma cell lines were purchased from the American Type Culture Collection (Manassas, VA, USA). The cells were grown adherently in Dulbecco’s modified Eagle’s medium (DMEM, Sigma-Aldrich China, Inc., Hong Kong, China) supplemented with 10% fetal bovine serum (FBS; Sigma-Aldrich China) and 1% penicillin-streptomycin (Gibco Life Technologies, Grand Island, NY, USA) and maintained in a humidified incubator containing 5% CO₂ at 37°C. The cells were maintained in these culture conditions for all experiments. Monoclonal antibodies used in the present study were as follows: Anti-β-actin (cat. no. 4967; Cell Signaling Technology, Inc., Danvers, MA, USA); anti-Glut1 (cat. no. sc-7903; Santa Cruz Biotechnology, Inc., Dallas, TX, USA) and anti-phosphoinositide-dependent kinase-1 (PDK1; cat. no. 3820; Cell Signaling Technology, Inc.). A vector containing Myc-DDK-tagged wild-type Glut1 (cat. no. RC222696), was purchased from OriGene Technologies, Inc., Rockville, MD, USA). Temozolomide (TMZ), 5-fluorouracil (5-FU) and paclitaxel (Taxol) were purchased from Sigma-Aldrich China, Inc.

Generation of Taxol- and TMZ-resistant cell lines. The Taxol- and TMZ-resistant cell lines were generated according to previously described methods (11,12). Briefly, U251 Taxol- or TMZ-resistant cells were developed from parental U251 cells by treating the cells with gradually increasing concentrations (0.1, 0.5, 1 and 2 µM) of Taxol or TMZ in regular cell culture medium. Taxol- or TMZ-resistant single clones were selected and pooled for the subsequent experiments. All resistant cells were re-selected by treatments every four weeks.

Cell viability assay. The Taxol- and TMZ-resistant cells were treated with the indicated concentrations of Taxol, 5-FU or TMZ (0.3, 1 and 0.1%, respectively) for 48 h. The cells were seeded in a 48-well plate, at a density of 1x10⁴ cells/well in 0.2 ml DMEM supplemented with 10% FBS. Following an overnight incubation under the same culture conditions, each well was refreshed with DMEM for a further 24 h. The cells were then treated with DMEM containing various concentrations of Taxol, TMZ, 5-FU, Taxol + TMZ, or Taxol + 5-FU. The therapeutic agent-containing DMEM was refreshed after two days, and the cells were incubated under the same conditions. Finally, cell viability was assessed using an MTT assay (Sigma-Aldrich, St. Louis, MO). Five hours prior to the end of the incubation time, 20 µl MTT solution [5 mg/ml dissolved in phosphate-buffered saline (PBS)] was added to each well containing cells, followed by incubation at 37°C for 5 h. The media were removed by aspiration with a needle and syringe, 200 µl dimethylsulfoxide was added to each well and formazan crystals were dissolved by continuous pipetting. Following incubation of the plate at 37°C for 5 min, the absorbance was measured at 590 nm using a plate reader (Multiskan™ GO; Thermo Fisher Scientific, Waltham, MA, USA). The relative viability was obtained from the absorbance at 590 nm of therapeutic agent-treated cells divided by the absorbance of untreated cells at 590 nm. The cell viability experiment was repeated three times.

Western blot analysis. The Taxol- and TMZ-resistant cells, as well as Taxol-, 5-FU- or TMZ-treated Taxol- and TMZ-resistant cells were harvested and lysed in a buffer containing 50 mM Tris-HCl (pH 7.5) 150 mM NaCl, 2 mM EDTA, 1% Triton X-100, 1 mM phenylmethylsulfonyl fluoride and Protease Inhibitor Cocktail (Sigma-Aldrich) for 20 min on ice. Lysates were cleared by centrifugation at 16873 x g for 10 min at 4°C. Supernatants were collected and protein concentrations were determined using the Bradford assay (Bio-Rad Laboratories, Inc., Hercules, CA, USA). The proteins (50 µg) were then separated by 10% SDS-PAGE and transferred to a nitrocellulose membrane (Bio-Rad Laboratories, Inc.). Following blocking in PBS containing 5% non-fat dry milk for 1 h, the membranes were incubated overnight at 4-8°C with the primary antibodies diluted in PBS (1:5,000) with 5% non-fat dry milk. The membranes were extensively washed with PBS, and incubated at room temperature for 1 h with horseradish peroxidase-conjugated secondary anti-mouse or anti-rabbit secondary antibodies (1:2,000; cat. no. SA00001-2; Proteintech Group, Inc., Chicago, IL, USA). Following additional washes with PBS, the antigen-antibody complexes were visualized using an enhanced chemiluminescence kit (Pierce Biotechnology, Inc., Rockford, IL, USA).

Glucose uptake assay. U251 cells and TMZ-treated U251 cells were seeded in 12-well plates at a density of 1-3x10⁴ cells/well. Culture media was collected at 48 h and stored at -20°C until assayed. Glucose uptake was measured using an Amplex Red Glucose/Glucose Oxidase Assay kit (Molecular Probes Life Technologies, Carlsbad, CA, USA). Absorbance was measured at 563 nm using a SpectraMax M5 plate reader (Molecular Devices, Life Technologies, Sunnyvale, CA, USA). The results were normalized to the quantity of total protein compared with that of the control cells.

Lactate production assay. Lactate production in the cell culture supernatant was detected using a Lactate Assay kit (BioVision, Inc., Milpitas, CA, USA). Results were normalized to the quantity of total protein compared with that of the U251 cells without TMZ treatment.

Plasmid DNA transfection. A vector containing wild-type Glut1 was purchased from OriGene Technologies, Inc. (cat. no. RC222696). Transfection was performed using the Oligofectamine Transfection reagent (Invitrogen Life Technologies, Carlsbad, CA, USA), according to the manufacturer's instructions. Taxol-resistant U251 cells at a density of 10⁵ cells/well in 0.2 ml DMEM were transfected with vector (1:1,000) and Glut1 (1:1,000). The cells were collected 48 h post-transfection and prepared for further analysis by western blotting and an MTT assay.

Statistical analysis. An unpaired Student's t-test was used to analyze the data. SPSS version 21.0 (International Business Machines, Armonk, NY, USA) was used for all statistical analyses. All values are expressed as the mean ± standard error. P<0.05 was considered to indicate a statistically significant difference between values.
Results

Treatment with TMZ decreases the glucose metabolism of glioma cells. A previous study demonstrated that TMZ-resistant glioma cells exhibited elevated mitochondrial function (13), thus suggesting that there is a link between cellular metabolism and TMZ-induced cell apoptosis. Therefore, the present study examined whether treatment of glioma cells with TMZ regulates cellular metabolism. Notably, glucose metabolism was significantly downregulated following treatment with TMZ at various concentrations (Fig. 1). U251 (Fig. 1A) and LN229 (Fig. 1B) cells exhibited decreased glucose uptake and lactate production following treatment with TMZ at low-toxic concentrations for 48 h. These results suggest that TMZ may be administered as an anticancer therapeutic agent through the inhibition of glucose metabolism in glioma cells.

TMZ-resistant glioma cells exhibit decreased glucose metabolism. To investigate the biological significance of TMZ-induced downregulation of glucose metabolism, TMZ-resistant cells were generated using U251 glioma cells, according to the methods of a previous study (12). Briefly, the cells were treated with gradually increasing concentrations of TMZ in cell culture medium and the TMZ-resistant cells were selected (14). After successive treatments for three months, numerous resistant cell clones were developed and pooled for the subsequent experiments. To verify TMZ resistance, the parental cells and resistant pool cells were treated with TMZ at various concentrations for 48 h. As was expected, a cell viability assay demonstrated that TMZ-resistant U251 cells tolerated markedly higher concentrations of TMZ, when compared with TMZ-sensitive cells, which exhibited significant inhibition of viability at 50, 100 and 200 µM (Fig. 2A). In addition, the glucose uptake and lactate production of the TMZ-resistant U251 cells were decreased (Fig. 2B). In addition, the expression levels of key enzymes associated with glycolysis were detected. Glut1 facilitates the transport of glucose across the plasma membranes of mammary cells, whereas PDK1 inactivates pyruvate dehydrogenase (PDH), which catalyzes the oxidative decarboxylation of pyruvate through the phosphorylation of PDH (15). The present study demonstrated that Glut1 and PDK1 were downregulated in TMZ-resistant cells (Fig. 2C), supporting the results presented in Fig. 2B demonstrating that TMZ-resistant glioma cells exhibit decreased glucose metabolism.

Taxol-resistant glioma cells display upregulated glucose metabolism. The combination of Taxol with numerous anticancer therapeutic agents has been assessed and clinically applied for the treatment of patients with cancer. To investigate the association between dysregulated glucose metabolism and chemosensitivity, a Taxol-resistant cell line was generated from U251 cells. Taxol-resistant U251 cells demonstrated a significant tolerance to Taxol at the doses of 0.5 µM, 1 µM and 5 µM (Fig. 3A). In addition, glucose uptake and lactate production (Fig. 3B) were detected in Taxol-sensitive and -resistant glioma cells. Taxol-resistant cells exhibited upregulated glucose metabolism, as compared with the Taxol-sensitive cells, suggesting that activated glucose metabolism may be an underlying mechanism of resistance, and may be a therapeutic target for overcoming Taxol resistance in patients with glioma. Concordantly, the expression levels of Glut1 and PDK1 were observed to be upregulated in the Taxol-resistant cells (Fig. 3C).

A combination of Taxol and TMZ exerts a synergistic effect on Taxol-resistant cells via inhibition of glucose metabolism. It has previously been reported that Taxol-resistant breast cancer cells exhibit upregulated glucose metabolism, and treatment with Taxol and glucose metabolism inhibitors demonstrated a greater inhibitory effect on breast cancer (11). The present study observed that treatment with TMZ inhibited glucose metabolism, however Taxol-resistant glioma cells exhibited activated glucose metabolism; therefore, it was hypothesized that a combination of TMZ and Taxol may act synergistically to overcome Taxol resistance via the inhibition of glucose metabolism.

metabolism. Experiments were designed to examine whether treating Taxol-resistant glioma cells with TMZ would result in synergistic therapeutic effects. As shown in Fig. 4A, no significant inhibitory effects were observed in the Taxol-resistant cells treated with Taxol or TMZ alone; however, administering a combination of Taxol and TMZ resulted in significant inhibition of cell viability. It has previously been reported that treatment with 5-FU may induce glucose metabolism in colon cancer cells and has similar regulatory effects on glucose metabolism as Taxol (15). Therefore, in the present study, resistant cells
were treated with a combination of Taxol and 5-FU; however, no improvement in the chemotherapeutic effects was noted (Fig. 4B), indicating that the synergistic inhibitory effects exerted by the combination of Taxol and TMZ may be due to the inhibition of glucose metabolism.

To support this conclusion, the glucose uptake and lactate production of the cells were determined following the combined treatment (Fig. 5A). The glucose uptake and lactate production were significantly decreased following treatment with a combination of Taxol and TMZ. To further verify the hypothesis, an expression vector containing Glut1 was transiently transfected into the Taxol-resistant U251 cells (Fig. 5B). Restoration of Glut1 expression recovered the glucose metabolism in U251 Taxol-resistant cells (data not shown), and rendered cells resistant to the combined treatment (Fig. 5B). These data indicate that the inhibition of glucose metabolism may specifically account for the synergistic effects of Taxol and TMZ combined treatment in Taxol-resistant glioma cells.

**Discussion**

Paclitaxel (Taxol) is one of numerous tumoricidal agents that target microtubules, and is widely administered as a chemotherapeutic agent in the treatment of various types of human cancer (16). The primary cellular targets of Taxol are cancer cell microtubules, which are vital for mitotic activity, cellular motility and proliferative capacity (17). However, despite an impressive initial clinical response, the majority of patients eventually develop resistance to Taxol. Therefore, the ability to reduce chemoresistance is particularly important for patients with cancer. One known mechanism associated with cancer cell resistance to Taxol, and other microtubule-stabilizing agents,
is the high expression of the membrane, P-glycoprotein, which functions as a drug-efflux pump (18). Other cellular mechanisms include cell cycle deregulation (19,20) and alterations to tubulin structure (21,22). A recent study reported that Taxol resistance in breast cancer cells was mediated by the hippo signaling pathway (23). In addition, a correlation between Aurora kinase A and Taxol resistance has been detected in a xenograft model of breast cancer (24). However, the detailed mechanisms for the development of Taxol resistance in glioma cells remain to be elucidated.

Cancer cells use aerobic glycolysis, with reduced mitochondrial oxidative phosphorylation, to metabolize glucose, whereas healthy cells rely on oxidative phosphorylation. Therefore, the metabolic dependencies of cancer cells may be exploited for cancer treatment via inhibition of metabolic enzymes, in order to improve the efficacy of cancer therapy and overcome therapeutic resistance. It has been reported that numerous anticancer agents may be combined with glycolysis inhibitors, such as 5-FU (25), cisplatin (26), daunorubicin (27), Taxol (28), trastuzumab (29) and doxorubicin (30), in order to exert a synergistic inhibitory effect on cancer cells. In addition, the inhibition of glucose uptake has been shown to sensitize cancer cells to daunorubicin, and resensitize drug-resistant cells (27). A previous study demonstrated that targeting dysregulated glucose metabolism in breast cancer cells led to reduced trastuzumab resistance (29). Furthermore, in vivo experiments demonstrated that 2-deoxy-D-glucose increased the efficacy of adriamycin in breast cancer patients with overexpression of the membrane, P-glycoprotein, which functions as a drug-efflux pump (18). Other cellular mechanisms include cell cycle deregulation (19,20) and alterations to tubulin structure (21,22). A recent study reported that Taxol resistance in breast cancer cells was mediated by the hippo signaling pathway (23). In addition, a correlation between Aurora kinase A and Taxol resistance has been detected in a xenograft model of breast cancer (24). However, the detailed mechanisms for the development of Taxol resistance in glioma cells remain to be elucidated.

The present study reported that a combination treatment with TMZ and Taxol sensitized Taxol-resistant glioma cells via the inhibition of glucose metabolism. Significant inhibition of glucose metabolism was observed in the TMZ-resistant cells, whereas increased glucose metabolism was observed in the Taxol-resistant cells. This phenotype triggered the investigation of the synergistic effects of a combination of these two chemotherapeutic agents. It has been reported that inhibition of glucose metabolism by oxamate resensitizes Taxol-resistant breast cancer cells to Taxol (11). Since TMZ was able to inhibit glucose metabolism, the present results demonstrate that treatment with TMZ enhances the cytotoxic effects on Taxol-resistant glioma cells by inhibiting glucose metabolism. A previous study reported that 5-FU treatment in cancer cells activated glucose uptake and lactate production (15). Conversely, in the present study, as compared with the combination of TMZ and Taxol, 5-FU treatment did not exert an improved inhibitory effect on glioma cells when combined with Taxol, thus suggesting that the inhibition of glucose metabolism may be the mechanism for the synergistic effect of TMZ and Taxol on Taxol-resistant cells. In addition, recovering the glycolysis signaling pathway by exogenous overexpression of Glut1 facilitated glioma cells with obtaining resistance to Taxol, indicating that dysregulated glucose metabolism may be the underlying mechanism of the synergistic effects of TMZ and Taxol. However, the detailed mechanisms are currently being investigated. The aim of future studies will be to screen additional chemotherapeutic agents and assess increasingly efficient chemotherapeutic strategies, and in vivo experiments will be performed to verify the results of animal models.

In conclusion, the present study provides a novel perspective on the synergistic effects of combined chemotherapeutic agents, and contributes to the development of clinical strategies for the treatment of patients with glioma.
