Abstract. Sepsis is a severe inflammatory response to systemic infection that frequently affects the myocardium. Previous studies have suggested that resveratrol (RESV) is protective in sepsis. The present study aimed to investigate the role of sirtuin 1 (Sirt1) signaling in the protective effect of intraperitoneally administered RESV against sepsis-induced myocardial injury. Cecal ligation and puncture, or a sham operation, were performed in male Sprague-Dawley rats, and the levels of tumor necrosis factor (TNF)-α and myeloperoxidase (MPO) were assessed by ELISA and an MPO activity kit, respectively. The extent of myocardial apoptosis was assessed by TUNEL staining. The protein expression levels of Sirt1, acetylated (Ac)-Forkhead box O1 (FoxO1), B cell lymphoma 2 apoptosis regulator (Bcl-2) and Bcl-2 associated protein X apoptosis regulator (Bax) were detected by western blot analysis. RESV was demonstrated to attenuate myocardial apoptosis and decrease the production of TNF-α and MPO. Additionally, RESV upregulated the expression of Sirt1 and Bcl-2, and downregulated the expression of Ac-FoxO1 and Bax. The protective effects of RESV were abolished by EX527, a Sirt1 inhibitor. RESV has therefore been demonstrated to attenuate myocardial injury in sepsis by decreasing neutrophil accumulation, TNF-α expression, and myocardial apoptosis via activation of Sirt1 signaling. These results suggest a novel therapeutic strategy for the clinical treatment of sepsis.

Introduction

Sepsis, characterized by whole-body inflammation, is caused by a severe systemic infection (1). Sepsis is a leading cause of mortality in critically ill patients and the predominant cause of mortality in non-coronary intensive care units (2-4). The overproduction of cytokines that are induced by an infectious stimulus is the hallmark of sepsis, and leads to multiple organ dysfunction and consequently to a high mortality (5). Myocardial dysfunction is a recognized manifestation of this lethal condition (6-8).

Resveratrol (RESV) is a polyphenolic phytoalexin that has previously been suggested to exert cardioprotective effects (9,10). It has been suggested to cause the ‘French Paradox’; the low incidence of cardiovascular diseases in the French population despite a high consumption of wine and saturated fat (11). In addition, RESV is reported to be beneficial for sepsis-induced myocardial dysfunction (12). However, the underlying mechanism remains unclear.

Sirtuin 1 (Sirt1), a member of the silent mating type information regulator family of proteins, has multiple protective effects in various diseases (13-15). Sirt1 suppresses cardiomyocyte apoptosis in diabetic cardiomyopathy (16) and is reported to suppress lung inflammasome activation in a murine model of sepsis (17). However, whether Sirt1 activation is involved in the protective effect of RESV against sepsis-induced myocardial dysfunction remains unclear.

The current study used a rat model of sepsis involving cecal ligation and puncture (CLP) to investigate whether RESV was protective against sepsis-induced myocardial injury. In addition, the role of Sirt1 was evaluated in this model of CLP-induced sepsis.

Materials and methods

Animals and reagents. The present study was approved by the Committee for Animal Research of the Fourth Military Medical University (Xi’an, China). All animal experiments were performed in accordance with the National Institutes
of Health Guidelines on the Use of Laboratory Animals (Bethesda, MD, USA). A total of 40 healthy, specific-pathogen-free, male Sprague-Dawley rats (age, 3 months; weight, 200-250 g), were obtained from the Animal Center of the Fourth Military Medical University (Xi’an, China). Rats were housed in constant humidity (50%) and temperature (25±2°C) animal facilities with free access to standard laboratory food and water with a 12 h light/dark cycle.

RESV was purchased from Sigma-Aldrich (Merck Millipore, Darmstadt, Germany). The Sirt1 inhibitor, EX527, was purchased from Tocris Bioscience (Bristol, UK). Rabbit antibodies against Sirt1 (cat. no. 9475), acetylated-Forkhead box O1 (Ac-FoxO1; cat. no. 2880), B cell lymphoma 2 apoptosis regulator (Bcl-2; cat. no. 2870), and Bcl-2 associated protein X apoptosis regulator (Bax; cat. no. 2772) were purchased from Cell Signaling Technology, Inc. (Beverly, MA, USA). Antibodies against glyceraldehyde 3-phosphate dehydrogenase (GAPDH; cat. no. BM1623), and goat-rabbit (for Sirt1, Ac-FoxO1, Bcl-2 and Bax; cat. no. BA1039) and goat anti-mouse (for GAPDH; cat. no. BA1089) secondary antibodies were purchased from Wuhan Boster Biological Technology, Ltd. (Wuhan, China).

CLP surgery. To establish sepsis, rats were subjected to a CLP procedure. Animals were generally anesthetized with chloral hydrate (Sigma-Aldrich; Merck Millipore) (350 mg/kg) via intraperitoneal injection, and an abdominal midline incision (2-3 cm) was created to expose the cecum. The cecum was exteriorized and isolated, and a midpiece ligation of the cecum was made using 4-0 silk. The cecum was then perforated below the ligation twice with an 18-gauge needle, and a small amount of stool was extruded through the puncture holes to ensure patency. The cecum was then relocated to its normal intra-abdominal position and the abdomen was closed by suturing the muscle and skin. For the sham-operated animals, the cecum was isolated without ligation and puncturing. All animals received 0.9% saline solution (40 ml/kg of body weight) subcutaneously immediately following the surgery and every subsequent 24 h.

Experimental protocol. A total of 40 rats were randomly divided into 5 groups of 8 animals: Sham operation without CLP; CLP; CLP + RESV; CLP + RESV + EX527; and CLP + EX527. RESV was administered intraperitoneally at 60 mg/kg per rat, at 3, 12 and 24 h post-surgery. The Sirt1 inhibitor, EX527, was dissolved in dimethyl sulfoxide and diluted to the final concentration with normal saline. The Sirt1 inhibitor, EX527, or the same volume of vehicle, was intraperitoneally injected at a dose of 5 mg/kg every two days, beginning 8 days prior to CLP surgery. A CLP + EX527 group was included to assess any contribution of EX527 to CLP-induced sepsis.

Hemodynamic assessment. Rats were anesthetized with chloral hydrate at 48 h post-CLP surgery, and pressure tracings of cardiac function were analyzed using an RM-6280 Multi-channel Physiological Signal Recording system (Chengdu Science Instrument Factory, Chengdu, China) for the assessment of cardiac function. A high-fidelity, pressure-transducing catheter, filled with heparinized saline, was inserted via the right carotid artery into the left ventricle. When the rats returned to a stable condition, hemodynamic changes, including left ventricular systolic pressure (LVSP) and left ventricular end-diastolic pressure (LVEDP), and their first derivative with respect to time (LVAdP/dt max) were measured continuously (over 3 different periods, 10 cardiac cycles for each).

Myocardial apoptosis. Rats were anesthetized with chloral hydrate and sacrificed by thoracotomy. Hearts were harvested at 48 h post-CLP surgery and fixed in 4% paraformaldehyde for 48 h. Following embedding in paraffin, 5 µm thick sections of whole hearts were obtained. Terminal deoxynucleotidyl transferase dUTP nick-end labeling (TUNEL staining) was used to assess the number of apoptotic myocardial cells. TUNEL kits were purchased from Roche Diagnostics GmbH (Mannheim, Germany). TUNEL reaction mixture (50 µl) was added to each sample and the slides incubated in a humidified atmosphere for 60 min at 37°C in the dark. Slides were rinsed with phosphate-buffered saline (PBS; pH 7.4) three times, for 5 min each time. To detect the nuclei, slides were incubated with 4',6-diamidino-2-phenylindole (DAPI) for 5 min at room temperature in the dark, rinsed with PBS three times, for 5 min each time, and observed under a fluorescence microscope. TUNEL-positive nuclei were green and DAPI-positive nuclei were blue. The percentage of apoptotic nuclei (apoptotic nuclei/total nuclei x100) was calculated in 5 randomly chosen fields per slide (3 slides per section and 3 sections per rat, 26 rats in total).

Detection of tumor necrosis factor (TNF)-α in the serum and myocardial tissue. Blood samples were collected from the abdominal aorta at the time of sacrifice 48 h post-CLP surgery and centrifuged (1,000 x g for 15 min) to obtain serum that was stored at -80°C prior to further analysis. Serum and heart samples, harvested and stored at -80°C until analysis, were processed to measure TNF-α levels with an enzyme-linked immunosorbent assay (ELISA) kit (cat. no. JER-06; Joyee Biotechnics Co., Ltd., Shanghai, China), used according to the manufacturer's protocol.

Evaluation of myeloperoxidase (MPO) levels. Myocardial tissues were collected 48 h after CLP surgery. An MPO Activity assay kit (cat. no. A044; Nanjing Jiancheng Bioengineering Institute, Nanjing, China) was employed to detect the level of MPO in the myocardial tissue.

Western blotting. Left ventricular myocardial tissue was lysed in sample buffer (Pulse Yuan Biological Technology Co., Ltd., Xi’an, China), homogenized, and centrifuged at 10,000 x g for 15 min. A bicinchoninic acid assay was performed for protein quantification. Equal amounts of total protein (40 µg) were separated on 10-15% denaturing gels by sodium dodecyl sulfate-polyacrylamide gel electrophoresis. The proteins were transferred onto nitrocellulose membranes (EMD Millipore, Billerica, MA, USA) and incubated in 10% skimmed milk in Tris-buffered saline and 0.1% Tween-20 (TBST) for 2 h. The membrane was then incubated with primary antibodies against Sirt1, Ac-FoxO1, Bcl-2, or Bax, diluted 1:1,000, at 4°C overnight. GAPDH was selected as the loading control. The blots were washed with TBST and incubated with the appropriate
secondary antibodies conjugated to horseradish peroxidase diluted 1:5,000, for 1 h at room temperature, and then washed with TBST. Immunoreactive bands were detected using an enhanced chemiluminescence detection reagent (Beijing Solarbio Science & Technology Co., Ltd., Beijing, China) using a Bio-Rad imaging system (Bio-Rad Laboratories, Inc., Hercules, CA, USA), and quantified using Quantity One software version 4.62 (Bio-Rad Laboratories, Inc.).

Statistical analysis. Data are presented as the mean ± standard error. Significant differences among groups were evaluated by Student’s t-test for unpaired data, or one-way analysis of variance followed by Dunnett’s t-test for multiple comparisons. P<0.05 was considered to indicate a statistically significant difference.

Results

**RESV attenuates sepsis-induced myocardial injury in rats.** CLP-induced sepsis resulted in a severe impairment in cardiovascular performance at 48 h post-CLP surgery. In the CLP group, the LVSP was significantly decreased (P<0.001; Fig. 1A), the LVEDP was significantly elevated (P<0.001; Fig. 1B), and LV±dP/dt max were significantly decreased compared with the sham group (P<0.001 and P<0.001, respectively; Fig. IC and D). Treatment with RESV significantly prevented all of these detrimental effects induced by CLP (P<0.05 CLP + RESV vs. CLP group; Fig. 1). EX527, a selective Sirt1 inhibitor, significantly attenuated the effects induced by RESV on LVSP, LVEDP and LV±dP/dt max (P<0.05, CLP + RESV + EX527 group vs. CLP + RESV group; Fig. 1). No significant difference was detected between the CLP and CLP+EX527 groups.

**RESV reduces myocardial apoptosis in septic rats.** The number of TUNEL-positive cells detected in myocardial tissue was increased in the CLP group compared with the sham group (P<0.001; Fig. 2), indicating a significantly higher degree of apoptosis. There was a significant reduction in TUNEL-positive staining in the RESV-treated group compared with the CLP group (P=0.0014; Fig. 2), indicating an anti-apoptotic effect of RESV. EX527 suppressed the protective effect of RESV; increasing the apoptotic index in the CLP + RESV + EX527 group compared with the CLP + RESV group (P=0.0038; Fig. 2). No significant difference was detected between the CLP and CLP+EX527 groups (P=0.9909).

**RESV suppresses the sepsis-induced production of TNF-α.** An inflammatory response accompanied the CLP-induced sepsis. In the CLP group, the level of TNF-α was significantly
AN et al: RESVERATROL ALLEVIATES MYOCARDIAL INJURY VIA Sirt1 SIGNALING IN RAT SEPSIS

5300

increased in serum (P<0.001; Fig. 3A) and myocardial tissue compared with the sham group (P<0.001; Fig. 3B). Treatment with RESV significantly decreased the levels of TNF-α in the CLP + RESV group compared with the CLP group in serum (P<0.001; Fig. 3A) and myocardial tissue (P<0.001; Fig. 3B). EX527 virtually eliminated the protective effect of RESV treatment in the CLP + RESV + EX527 group compared with the CLP + RESV group in serum (P<0.001; Fig. 3A) and myocardial tissue (P<0.001; Fig. 3B). No significant difference was detected between the CLP and CLP+EX527 groups (P=0.9992) in serum; however, in the myocardial tissue, EX527 significantly decreased the level of TNF-α compared with the CLP group (P=0.0008).

RESV inhibits neutrophil infiltration of myocardial tissue in septic rats. MPO, a heme protein predominantly expressed in neutrophils, is synthesized and stored in azurophilic granules of granulocytes and monocytes, and accounts for 5% of dry cell weight (18-20). The extent of neutrophil infiltration is partially reflected by the activity of MPO within a tissue. As demonstrated in Fig. 4, the activity of MPO in hearts from the CLP group was significantly increased compared with sham group (P=0.0004). By contrast, the activity of MPO was significantly reduced in the CLP + RESV group compared with the CLP group (P=0.0372). Furthermore, this effect was largely abolished by EX527 in the CLP + RESV + EX527 group compared with the CLP + RESV group (P=0.0130), indicating that the activation of Sirt1 may have an important role in the protective effect of RESV. No significant difference was detected between the CLP and CLP+EX527 groups (P=0.9878).

Expression and effect of Sirt1 in septic rats treated with RESV. To investigate the role of Sirt1 in injured myocardial tissue of rats with CLP-induced sepsis, the protein expression levels of Sirt1, Ac-FoxO1, Bcl-2 and Bax were assessed by western blot analysis (Fig. 5). The CLP group displayed significantly lower Sirt1 expression (P<0.001; Fig. 5A), higher Ac-FoxO1 expression (P<0.001; Fig. 5B), lower Bcl-2 expression (P<0.001; Fig. 5C) and higher Bax expression (P<0.001; Fig. 5D) than the sham group. RESV prevented the CLP-induced downregulation of Sirt1 and Bcl-2 expression in the CLP + RESV group compared with the CLP group (P<0.001 and P<0.001, respectively; Fig. 5A and C), and, similarly, prevented CLP-induced upregulation of Ac-FoxO1 and Bax (P<0.001 and P<0.001, respectively; Fig. 5B and D). In the CLP + RESV + EX527 group, all protective effects of RESV were prevented compared with the CLP + RESV group (P<0.05; Fig. 5). No significant differences in Sirt1, Ac-FoxO1 and Bcl-2 were detected between the CLP and CLP+EX527 groups (P=0.9969, P=0.5170 and P=0.9936, respectively); however, Bax was significantly decreased with the application of EX527 (P<0.001). This suggested that Sirt1 is important for the protective effect of RESV against CLP-induced myocardial injury.

Discussion

In the present study, a CLP-induced rat model of sepsis was established to mimic human sepsis, and used to investigate sepsis-induced cardiac dysfunction and the protective effect of RESV. Treatment with RESV was demonstrated to significantly suppress myocardial apoptosis, neutrophil...
infiltration and TNF-α production during sepsis. Additionally, Sirt1 was demonstrated to be involved in the cardioprotective effect of RESV.

Sepsis is a lethal condition characterized by a systemic inflammatory response syndrome, induced by a severe infection leading to multiple organ dysfunctions (21-23). The cardiovascular system is frequently affected by sepsis, and this effect has been studied for nearly six decades (23). Patients with sepsis and myocardial depression are at a 50-70% greater risk of death than patients without cardiovascular complications (23), indicating that myocardial injury is an urgent problem to resolve. The underlying mechanisms of sepsis-induced myocardial dysfunction are thought to include metabolic changes (24), autonomic dysregulation (25), mitochondrial dysfunction (26), cell apoptosis (27), and inflammation (28). TNF-α is important during sepsis-induced inflammation (29). It has previously been reported that the application of murine monoclonal anti-TNF antibodies induced a transient improvement in ventricular function in patients with sepsis, suggesting that TNF may be involved in sepsis (30). Furthermore, TNF-α exerts a negative inotropic effect on the heart, leading to a decrease in blood pressure and cardiac output (29). TNF-α can also activate other inflammatory cells, such as neutrophils, triggering an inflammatory cascade (31). Thus, neutrophil infiltration is another factor associated with myocardial dysfunction induced by sepsis (32).

RESV, a natural phenolic anti-oxidant, has therapeutic benefits in sepsis (12,33-35). Recently, RESV was reported to attenuate microvascular inflammation in sepsis (36). Additionally, RESV was suggested to suppress high-mobility group protein box 1 nucleocytoplasmic translocation in sepsis-induced liver injury (13) and to alleviate sepsis-induced myocardial dysfunction via the Nrf2 transcription factor (35). In the present study, RESV was suggested to ameliorate myocardial dysfunction, suppress TNF-α activity in the serum and myocardium, and inhibit neutrophil accumulation in the myocardial tissue.

EX527 abolished the protective effect of RESV, indicating Sirt1 activation is closely associated with the RESV mechanism of action. Sirt1, a nicotinamide adenine dinucleotide+-dependent class III histone deacetylase, is involved in numerous pathophysiological processes. Sirt1 is essential for protein deacetylation and the regulation of pro-inflammatory cytokine release, apoptosis, stress resistance, metabolism, mitochondrial biogenesis, autophagy, senescence, differentiation and aging (9,37-39). The activation of Sirt1 leads to the deacetylation and activation of FoxO, which promotes the synthesis of superoxide dismutase and catalase (40), therefore protecting the cell against oxidative stress. In addition, Sirt1 upregulates Bcl-2 expression and downregulates Bax expression, leading to an anti-apoptotic effect (41). In accordance with previous studies (42-44), the results of the present study suggest that RESV suppresses myocardial apoptosis by upregulating Bcl-2 expression and downregulating Bax expression. In addition, RESV promoted the deacetylation and activation of FoxO1, as evidenced by the decrease in Ac-FoxO1 detected by western blotting. However, the selective Sirt1 inhibitor, EX527, abolished the protective effects of RESV, indicating the involvement of Sirt1 in this protective effect. The inclusion of the control group, CLP + EX527, throughout the study additionally excluded any contribution of EX527 itself to either the CLP-induced sepsis or the RESV-induced protections.
In conclusion, the results of the present study demonstrate that RESV ameliorates cardiac dysfunction and apoptosis induced by sepsis, and suppresses TNF-α production and neutrophil accumulation. Additionally, activation of Sirt1 signaling is involved in the protective effects of RESV. The present study, therefore, provides evidence supporting further investigations into the clinical use of RESV in the treatment of sepsis-induced myocardial injury.
