Abstract. β-catenin protein exhibits a dual function in epithelial cells, depending on its intracellular localization. At the plasma membrane, β-catenin is an important constituent of adherens junctions. However, when the Wnt/β-catenin signaling pathway is activated, β-catenin translocates to the nucleus to promote specific gene expression. To investigate the functional activity and examine the role of the Wnt/β-catenin signaling pathway in various human prostate cancer cells, indirect immunofluorescence was performed to detect the expression and distribution of β-catenin in the following prostate cancer cell lines: PC-3, LNCaP, C4-2, IA8-ARCaP and IF11-ARCaP. A marked difference was observed in the expression and distribution of β-catenin in different prostate cancer cell lines. β-catenin was observed in the nuclei of IA8-ARCaP and IF11-ARCaP cell lines, whereas it was present on the membrane of LNCaP and C4-2 cell lines. There was a low expression of β-catenin in the PC-3 cell line. Furthermore, short hairpin RNA (shRNA) targeting human β-catenin was constructed to investigate the effect of β-catenin shRNA on the proliferation and invasive potency of prostate cancer cells. The IA8/β-catenin(-) cell line exhibited a reduced potency for invasion and proliferation compared with the IA8 and IA8-shControl groups. The present study demonstrated that the activation of the Wnt/β-catenin signaling pathway may be responsible for their high invasive potency.

Introduction

PCa is the second most frequent cause of cancer-associated mortality in males in the USA (1). Various growth factors and cytokines have been reported to be associated with the progress of PCa; however, the exact underlying molecular mechanism of PCa development and progression remains to be fully elucidated.

The Wnt/β-catenin signaling pathway regulates pattern formation during embryogenesis and tumor progression. This signaling pathway activates various distinct intracellular pathways, which are involved in the proliferation, differentiation and polarity of cells. Aberrant activation of the Wnt/β-catenin signaling pathway has been associated with tumor development and metastasis in numerous types of cancer (2-4).

During epithelial mesenchymal transition (EMT), epithelial cells alter morphologically, resulting in a loss of polarity and cell-to-cell contact. It has previously been demonstrated have indicated that during tumor progression, EMT is crucial for the invasion and metastasis of tumor cells (5). Our present study demonstrated that the activation of the Wnt/β-catenin signaling pathway is associated with the process of EMT and its role in the invasion and proliferation of tumor cells (6). The Wnt/β-catenin signaling pathway was involved in EMT of human PCa induced by hypoxia-inducible factor (HIF) 1-α (7). The current hypothesized that the aberrant activation of the Wnt/β-catenin signaling pathway may be involved the proliferation and invasive potency of PCa. The present study aimed to investigate the expression and distribution of β-catenin in different prostate cancer cell lines. It was demonstrated β-catenin acted as an adhesion molecule in the LNCaP and C4-2 cell lines, and as a transcription factor of the Wnt/β-catenin signaling pathway in the IF11-ARCaP and IA8-ARCaP cell lines. The results of the present study suggested that the aberrant activation of the Wnt/β-catenin signaling pathway in IA8-ARCaP and IF11-ARCaP may be responsible for their high invasive potency.

RNA interference (RNAi) specifically inhibits the transcription of target genes, thus, reducing the corresponding protein levels, and has a high efficiency and specificity. In the present study, small hairpin (shRNA) targeting β-catenin was used to investigate the role of the Wnt/β-catenin signaling pathway in human PCa cells in vitro.

Materials and methods

Cell culture and plasmids. PC-3, LNCaP, C4-2, IA8-ARCaP and IF11-ARCaP human PCa cell lines were obtained from Professor Dalin He, Xi'an Jiaotong University (Xi'an, China).

Western blotting. Total protein was isolated from cultured cells using 300 ml ice cold lysis buffer containing 1% NP-40, 50 mmol/l Tris (pH 7.4), 150 mmol/l NaCl, 0.1% sodium dodecyl sulfate, 0.5% deoxycholate, 200 mg/ml phenylmethylsulfonyl fluoride and 50 mg/ml aprotinin. Insoluble materials were removed by ultracentrifugation at 15,000 x g for 30 min at 4˚C. The concentration of the extracted protein was measured spectrophotometrically with Coomassie G-250. Total protein (50 µg) was loaded in each lane and resolved by 29 cycles of 94˚C for 30 sec, 58˚C for 30 sec and 72˚C for 2 min. Reactions were finished with a 72˚C, 10 min extension step. PCR products were visualized by electrophoresis on 1.2% agarose gels and quantified with Quantity One software (version 4.6.6), normalized against GAPDH, and presented as a ratio of control.

Reverse transcription-polymerase chain reaction (RT-PCR). Total RNA was extracted from the cell lines at 80-90% confluence using TRIzol® (Invitrogen; Thermo Fisher Scientific, Inc.). RNA (1 µg) was reverse transcribed using a RevertAid First Strand cDNA Synthesis kit (Fermentas; Thermo Fisher Scientific, Inc.). Amplification of 2 µl cDNA was performed using Taq polymerase (Takara Bio, Inc., Otsu, Japan) with specific primers for β-catenin and β-actin (Table II). All primers were obtained from Sunbiotech. All PCR reactions were initiated with an incubation at 94˚C for 2 min, followed by 29 cycles of 94˚C for 30 sec, 58˚C for 30 sec and 72˚C for 2 min. Reactions were finished with a 72˚C, 10 min extension step. PCR products were visualized by electrophoresis on 1.2% agarose gels and quantified with Quantity One analyzing software (version 4.6.6), normalized against β-actin, and presented as a ratio of control. All assays were performed at least 3 times.

Indirect immunofluorescence. To detect the expression and distribution of β-catenin, PCa cells were fixed in 10% paraformaldehyde for 30 min and blocked with goat serum (Santa Cruz Biotechnology, Inc.) for 30 min. Cells were then incubated at 37˚C for 1 h with a mouse anti-human β-catenin monoclonal antibody (1:200; Santa Cruz Biotechnology, Inc.; sc-7963). Following three washes with PBS, cells were incubated with a fluorescence isothiocyanate-conjugated goat anti-mouse antibody (1:100; Santa Cruz Biotechnology, Inc.; sc-3692) at 37˚C for 1 h. The fluorescence staining intensity and intracellular location were examined by fluorescence microscopy.
The MTT assay was used to determine the proliferation of human PCa cells. PCa cells were seeded in 96-well plates and transfected with β-catenin shRNA. At various time points (24, 48 and 72 h), 50 ml 2.5 ng/ml thiazolyl blue tetrazolium bromide (MTT) solution was added into the cell culture plate and incubated with cells for an additional 4 h. The media was collected separately from each chamber, and cell-associated MTT crystal was dissolved separately in dimethyl sulfoxide on a shaker at room temperature.

Statistical analysis. Data are presented as the mean ± standard deviation. All data analyses were performed using SPSS software version 13.0 for Windows (SPSS, Inc., Chicago, IL, USA). One-way analysis of variance (ANOVA) and independent-samples t-tests were conducted. Tukey’s test was used for post hoc test following the ANOVA. All experiments were performed at least three times with similar results. *P<0.05 was considered to indicate a statistically significant difference.

Results

Expression and distribution of β-catenin in different PCa cell lines. β-catenin is a multifunctional protein involved in two processes, cell-to-cell adhesion and the Wnt/β-catenin signaling pathway. To investigate the functional activities of the Wnt/β-catenin signaling pathway in different PCa cells, the present study performed indirect immunofluorescence to detect the expression and distribution of β-catenin protein in PC-3, LNCaP, C4-2, IA8-ARCaP and IF11-ARCaP cell lines.

As presented in Fig. 1, there were marked differences in the expression and distribution of β-catenin between these cell lines. β-catenin was observed in the cytoplasm and nuclei of IA8-ARCaP and IF11-ARCaP cells, whereas it appeared to be present in the membrane of LNCaP and C4-2 cells. There was low expression of β-catenin in the PC-3 cell line. Therefore, β-catenin may act as an adhesion molecule in the LNCaP and C4-2 cell lines, and as a transcription factor of the Wnt/β-catenin signaling pathway in IF11-ARCaP and IA8-ARCaP cell lines. This data indicated that the functional activities of the Wnt/β-catenin signaling pathway in IF11-ARCaP and IA8-ARCaP cell lines was greater compared with PC-3, LNCaP and C4-2 cells. IA8-ARCaP was therefore used as the cell model to further investigate the role of the Wnt/β-catenin signaling pathway in PCa.

Inhibition of mRNA expression by β-catenin shRNA. Our previous study successfully constructed β-catenin shRNA using gene recombination technology, which significantly decreased the expression of β-catenin in HEK-293 cell lines (6). In the present study, the effects of β-catenin shRNA on the expression of β-catenin mRNA in IA8-ARCaP cell lines were investigated. Fig. 2A reveals the levels of β-catenin mRNA in IA8, IA8-shControl and IA8/β-catenin(-) cell lines, as measured by RT-PCR. Statistical analysis demonstrated that
the β-catenin mRNA expression levels in the IA8/β-catenin(-) cell line was significantly downregulated compared with IA8 cells (P=0.002; Fig. 2B). There was no significant difference between the IA8-shControl and IA8 groups.

Inhibition of β-catenin protein expression by β-catenin shRNA. To further investigate the inhibitory effects of β-catenin shRNA on the Wnt/β-catenin signaling pathway, the present study detected the expression of β-catenin protein using western blot analysis. The level of β-catenin protein in IA8, IA8-shControl and IA8/β-catenin(-) cell lines is presented in Fig. 3A. Statistical analysis revealed that the protein expression levels of β-catenin in IA8/β-catenin(-) was significantly decreased compared with IA8 and IA8-shControl group (P=0.029; Fig. 3B). There was no significant difference between the IA8-shControl and IA8 groups.

β-catenin regulates cell proliferation. As malignancy is associated with increasing cancer cell proliferation and invasion, the present study investigated the effect of β-catenin knockdown on proliferation in IA8-ARCaP cell lines. The growth potency of IA8, IA8/β-catenin(-) and IA8-shControl cells were assessed by MTT assay. As presented in Fig. 4, IA8/β-catenin(-) cells exhibited a reduced growth potency compared with IA8-shControl and IA8/β-catenin(-) cells (P<0.05 vs. IA8 and IA8-shControl). Data are expressed as the mean ± standard deviation. IA8/β-catenin(-), IA8-ARCaP cells transfected with β-catenin shRNA; IA8-shControl, IA8-ARCaP cells transfected with control shRNA.

β-catenin regulates cell invasion. To further examine the role of the Wnt/β-catenin signaling pathway in cell invasion of human PCA cells, a Matrigel Transwell assay was performed in vitro. The IA8, IA8/β-catenin(-) and IA8-shControl cells were seeded onto Matrigel-coated filters. The number of cells on the underside of the filter was determined after 48 h. Transfection with β-catenin shRNA resulted in a significant inhibition of IA8 cell invasion. Data are expressed as the mean ± standard deviation (n=3). **P<0.05 vs. IA8 and IA8-shControl groups. shRNA, short hairpin RNA; IA8/β-catenin(-), IA8-ARCaP cells transfected with β-catenin shRNA; IA8-shControl, IA8-ARCaP cells transfected with control shRNA.

Discussion

β-catenin inhibits cell proliferation in vitro. The proliferation of IA8, IA8-shControl and IA8/β-catenin(-) cells was analyzed using an MTT assay. IA8/β-catenin(-) cells exhibited a reduced growth potency compared with IA8-shControl and IA8/β-catenin(-) cells. **P<0.05 vs. IA8 and IA8-shControl. Data are expressed as the mean ± standard deviation. IA8/β-catenin(-), IA8-ARCaP cells transfected with β-catenin short hairpin RNA; IA8-shControl, IA8-ARCaP cells transfected with control short hairpin RNA.

β-catenin inhibits cell invasion in vitro. To further examine the role of the Wnt/β-catenin signaling pathway in cell invasion of human PCA cells, a Matrigel Transwell assay was performed in vitro. The IA8, IA8/β-catenin(-) and IA8-shControl cells were seeded into the upper chambers and 1 ml RPMI-1640 containing 20% FBS was added to the lower chambers. Cells were allowed to migrate for 48 h. As presented in Fig. 5, the number of invading cells in the IA8/β-catenin(-) group was significantly reduced compared with the IA8 and IA8-shControl groups (P=0.002). The results of the Matrigel Transwell assay demonstrated that inhibition of the Wnt/β-catenin signaling pathway via β-catenin shRNA may result in an inhibition of PCA cell invasion in vitro.

Discussion

β-catenin inhibits cell proliferation in vitro. The proliferation of IA8, IA8-shControl and IA8/β-catenin(-) cells was analyzed using an MTT assay. IA8/β-catenin(-) cells exhibited a reduced growth potency compared with IA8-shControl and IA8/β-catenin(-) cells. **P<0.05 vs. IA8 and IA8-shControl. Data are expressed as the mean ± standard deviation. IA8/β-catenin(-), IA8-ARCaP cells transfected with β-catenin shRNA; IA8-shControl, IA8-ARCaP cells transfected with control shRNA.

β-catenin inhibits cell invasion in vitro. To further examine the role of the Wnt/β-catenin signaling pathway in cell invasion of human PCA cells, a Matrigel Transwell assay was performed in vitro. cell-to-cell adhesion via binding to E-cadherin, and along with α-catenin to the actin cytoskeleton. In addition, β-catenin acts as a key component of the Wnt/β-catenin signaling cascade in the nucleus. Wnt protein binding to the seven-pass transmembrane receptors known as Frizzled proteins activates the signaling pathway, leading to β-catenin stabilization in the cytoplasm. Stabilized β-catenin subsequently translocates to the nucleus, where it associates with T cell factor/lymphoid enhancer factor-1 and promotes specific gene expression. Multiple key oncogenic proteins, including c-Myc, cyclin D1 and cyclooxygenase-2 have been reported to be regulated by the Wnt/β-catenin signaling pathway (8).

The aberrant activation of the Wnt/β-catenin signaling pathway in premalignant and malignant cells results in uncontrolled cell proliferation, growth and survival of cancer cells, and therefore cancer progression. The Wnt/β-catenin signaling pathway is a direct driver of thyroid transcription factor-1 expression, which is a tissue-specific transcription factor essential for thyroid differentiation (9). Dickkopf-related protein-1 (DKK-1), a secreted protein that binds to low density lipoprotein-related receptors 5/6, blocks Wnt-1 protein signaling. Accumulation of DKK1 and cytoplasmic/nuclear β-catenin in triple negative breast cancers is indicative of poor prognosis. DKK1 expression alone or in conjunction with β-catenin may identify patients who may benefit from early systemic treatment (10). In addition, the canonical Wnt/β-catenin signaling pathway regulates self-renewal of cancer stem cells and drug resistance of cancer cells (11,12).

Previous studies have suggested that the Wnt/β-catenin signaling pathway may be important in PCa. Chen et al (4) demonstrated that high levels of Wnt-1 and β-catenin expression were associated with advanced, metastatic, hormone-refractory PCa, and may serve as biomarkers of disease progression. Another study indicated that promoting Wnt/β-catenin activity via blocking DKK-1 promoted osteoblastic activity in osteolytic PC-3 cells, which suggested that the Wnt/β-catenin signaling pathway contributed to the osteoblastic phenotype of PCa cell bone metastasis (13).

EMT is important for cancer growth and invasion. Our previous study demonstrated that the Wnt/β-catenin signaling pathway is involved in EMT in human PCa and may be induced by HIF-1α (5). In the current study, the role of the Wnt/β-catenin signaling pathway in human PCa growth and invasion was investigated. Indirect immunofluorescence was used to detect the expression and distribution of β-catenin, the key component of the Wnt/β-catenin signaling pathway in different human PCa cell lines. The results of the present study indicated that in the LNCaP C4-2 cell lines, β-catenin localized in the membrane, whereas in the IAA8-ARCaP and IFI11-ARCaP cell lines, it was localized in the cytoplasm and nucleus. There was low expression of β-catenin in the PC-3 cell line. The EMT-positive cell lines IAA8-ARCaP and IFI11-ARCaP exhibited a greater level of cytoplasmic and nuclear β-catenin compared with the EMT-negative cell lines PC-3, LNCaP and C4-2. The activity of the Wnt/β-catenin signaling pathway in the more invasive PCa cells IAA8-ARCaP and IFI11-ARCaP was markedly greater compared with LNCaP and C4-2 cells. IAA8-ARCaP and IFI11-ARCaP were established from the ascites of a patient with widely disseminated disease that represented a lethal form of human PCa with the ability to invade and metastasize aggressively to bone and soft tissue (14). The results of the present study suggested that the high functional activity of the Wnt/β-catenin signaling pathway in IAA8-ARCaP and IFI11-ARCaP may be responsible for their high invasive potency.

RNA interference is the process of post-transcriptional, sequence-specific gene silencing in plants and animals, which was first introduced by Fire et al (15) in 1998, via experimentation in Caenorhabditis elegans. The process is initiated by shRNA homologous in sequence to the particular gene to be silenced. RNA interference is now a tool extensively employed in genetic engineering as a simple and effective gene knockdown technique. shRNA is an artificial RNA molecule with a tight hairpin turn that may be used to silence target gene expression via RNAi. shRNA is an advantageous mediator of RNAi in that it has a relatively low rate of degradation and turnover (15,16). To further investigate the role of the Wnt/β-catenin signaling pathway in PCa cells, β-catenin shRNA was used to suppress the activity of the Wnt/β-catenin signaling pathway in IAA8-ARCaP cell lines. The results demonstrated that the β-catenin-specific shRNA significantly suppressed the mRNA and protein expression levels of β-catenin, confirming that β-catenin shRNA may significantly inhibit the activity of the Wnt/β-catenin signaling pathway.

As malignancy has been associated with increased cancer cell proliferation and invasion, the present study investigated the effects of β-catenin shRNA on proliferation and invasion. An MTT assay indicated that knockdown of β-catenin significantly inhibited the proliferation of the IAA8-ARCaP cell line. A Matrigel Transwell assay revealed that β-catenin knockdown significantly suppressed the invasive activity of the IAA8-ARCaP cell line, which suggested that the Wnt/β-catenin signaling pathway regulated the proliferation and invasion of the IAA8-ARCaP cell line. The data indicated that the high functional activity of Wnt/β-catenin signaling in IAA8-ARCaP cells was responsible for its high invasive potency.

In conclusion, the present study demonstrated that suppressing the functional activity of the Wnt/β-catenin signaling pathway via β-catenin shRNA results in an inhibition of PCa proliferation and invasion. The results suggested that disrupting the Wnt/β-catenin signaling pathway may represent an opportunity for rational and novel drug design for the treatment and prevention of PCa.
