Abstract. Our previous studies revealed that REIC/Dkk-3 was expressed various tissues, including skin keratinocytes. The aim of the present study was to identify the factors that regulate the expression of the dickkopf Wnt signaling pathway inhibitor 3 (REIC/Dkk-3) tumor suppressor gene in normal human skin keratinocytes (NHKs). Several growth factors and cytokines that have previously been reported to be involved in the growth and differentiation of keratinocytes were screened as potential regulators. Western blot analysis was performed using protein from NHKs cultured with/without various factors including the epidermal growth factor, tumor necrosis factor-α, transforming growth factor-β, interleukin (IL)-1F9, IL-6, IL-8 and Ca2+. The results indicated that only TNF-α downregulated REIC/Dkk-3 expression in NHKs. Subsequently, TNF-α was confirmed to reduce the expression levels of REIC/Dkk-3 in mouse skin tissue and hair culture models. TNF-α-mediated downregulation of REIC/Dkk-3 expression in NHKs was abrogated by the addition of a TNF-α-specific antibody. In conclusion, the results indicate that TNF-α downregulates REIC/Dkk-3 expression in normal skin keratinocytes.

Introduction

Dickkopf Wnt signaling pathway inhibitor 3 (Dkk-3) is a member of the dickkopf (Dkk) family, and is also known as REIC due to its reduced expression in immortalized cells (1). Overexpression of REIC/Dkk-3 using an adenovirus vector has been demonstrated to induce growth suppression and/or apoptosis in a variety of cancer cells (2,3). Other Dkk family members, including Dkk-1, Dkk-2 and Dkk-4, interfere with the Wnt signaling pathway (4); however, the physiological function of REIC/Dkk-3 remains unclear. Previous studies investigating the expression pattern of REIC/Dkk-3 in normal and pathological skin tissues have demonstrated that the expression levels of REIC/Dkk-3 were evidently reduced, not only in skin cancer cells, but also in the normal skin keratinocytes surrounding cancer nodules (5,6). In addition, the level of REIC/Dkk-3 expression was reduced in normal skin keratinocytes under inflammatory conditions (5). Other researchers also reported that negative or very low expression of REIC/Dkk-3 was observed in cutaneous squamous cell carcinoma tissues (7). However, the role of REIC/Dkk-3 in normal and/or cancer skin tissues is still unclear. Furthermore, cornified skin tissues were observed to express REIC/Dkk-3 at varying levels (6). These previous findings indicate that normal and/or cancer cells secrete a factor(s) that regulates REIC/Dkk-3. These unknown regulators of REIC/Dkk-3 expression may be potential therapeutic targets for skin cancer. Therefore, the aim of the present study was to identify the factors involved in the regulation of REIC/Dkk-3 in normal skin keratinocytes.

Materials and methods

Reagents. Recombinant human epidermal growth factor (EGF), transforming growth factor-β (TGF-β), tumor necrosis factor-α (TNF-α) and interleukin (IL)-6 were purchased from Peprotech, Inc. (Rocky Hill, NJ, USA). Recombinant IL-1F9 and IL-8 were purchased from R&D Systems, Inc. (Minneapolis, MN, USA).

Animals. A total of 12 female C57BL/6 mice (age, 6-8 weeks; body weight, 16-22 g) were purchased from Clea Japan, Inc. (Hamamatsu, Japan) and maintained at 18-23°C with 40% humidity and a 12 h light/12 h dark cycle. Mice were fed with a normal mouse diet supplied by Clea Japan, Inc. and sacrificed using excess amount of the anesthetic drug. For anesthesia, 2,2,2-tribromoethanol (cat. no. T1420; Tokyo Chemical Industry Co., Ltd., Tokyo, Japan) was injected intraperitoneally at a dose of 200 mg/kg body weight. Animal experiments were approved and performed in accordance with the guidelines and regulations of the Animal Testing Committee of Okayama University.
with the guidelines of Okayama University (Okayama, Japan; permit no. OKU-2011105).

Cell culture. Normal human keratinocytes (NHKs) were purchased from Kurabo Industries, Ltd. (cat. no. KK-4009; Osaka, Japan) and cultured in HuMedia-KG2 (Kurabo Industries, Ltd.). NHKs were maintained at 37˚C with 5% CO₂ and incubated with 10 ng/ml of a specific neutralizing antibody against TNF-α (cat. no. D2H4; monoclonal rabbit antibody; Cell Signaling Technology, Inc., Danvers, MA, USA) for 24 h to abrogate TNF-α activity. Treatment of NHKs with the aforementioned recombinant protein factors was achieved by culturing NHKs with various concentrations of EGF (0, 10, 50 and 100 ng/ml), TGF-β (0, 1, 5, 10 ng/ml), TNF-α (0, 10, 50 and 100 ng/ml), IL-6 (0, 10, 50 and 100 ng/ml), IL-8 (0, 10, 50 and 100 ng/ml), IL-1F9 (0, 10, 50 and 100 ng/ml) and Ca²⁺ (0, 0.5, 1.5 and 5 mM) for 24 h. The concentrations used in the experiments were determined by previous studies (8,9).

Tissue culture. Mice were clipped and skin tissue was collected from the back using an 8 mm biopsy punch (Maruho, Co., Ltd., Osaka, Japan). As shown in Fig. 1A, the mouse skin tissue was then placed on a piece of filter paper (Advantec MFS, Inc., Tokyo, Japan), and both edges of the paper were immersed in Dulbecco's modified Eagle's medium (Thermo Fisher Scientific, Inc., Waltham, MA, USA) supplemented with 10% fetal bovine serum, 100 µg/ml kanamycin (Meiji Seika Pharma Co., Ltd., Tokyo, Japan) and 0.5 µg/ml amphotericin B (Gibco;Thermo Fisher Scientific, Inc.). Hematoxylin and eosin staining of frozen tissue sections was performed using conventional methods (5,6). Preliminary experiments demonstrated that the structure of skin tissue on the filter paper was maintained for 24 h (Fig. 1B). Skin tissue extracts were treated without or with 100 ng/ml recombinant TNF-α. Hair follicles were plucked from the mouse upper lip with tweezers and incubated in the φ 35 mm culture dish (Corning Incorporated, Corning, NY, USA) without or with 100 ng/ml TNF-α in Dulbecco's modified Eagle's medium supplemented with 10% fetal bovine serum, 100 µg/ml kanamycin and 0.5 µg/ml amphotericin B for 24 h.

Immunocytochemical and immunohistochemical analyses. Immunocytochemical detection of REIC/Dkk-3 in NHKs cultured on glass slide culture vessels (Thermo Fisher Scientific, Inc.) and tissue culture specimens was conducted as described previously (5,6). Briefly, samples were fixed in cold aceton for 10 min, washed with phosphate-buffered saline containing 0.05% Tween 20 (PBST), and incubated with a blocking solution (10% skim milk, 6% glycerine and 0.01 N KOH in PBST) at room temperature for 1 h. Subsequently, the slides were incubated with goat polyclonal antibody against REIC/Dkk-3 (cat. no. AF1118; R&D Systems, Inc.) at a 1:50 dilution at room temperature for 1 h. Subsequent to washing with PBST, the tissue sections were then incubated with the blocking solution, followed by probing with polyclonal donkey antibody against goat IgG (H+L) labeled with Alexa Fluor 488 dye (cat. no. A11055; Thermo Fisher Scientific, Inc.) at a 1:500 dilution. After washing with PBST, the tissue sections were mounted using VECTASHIELD with DAPI (Vector Laboratories, Inc., Burlingame, CA, USA). Normal goat IgG was used as a negative control for the primary antibody.

Preparation of protein lysates and western blot analysis. Protein extracts (10 µg) were obtained by lysing cells in mammalian protein extraction reagent (M-PER; Thermo Fisher Scientific, Inc.), and were subsequently used for western blot analysis. Protein from the tissue culture medium was prepared as described previously (10). Briefly, the culture medium was mixed with an equal volume of acetone and incubated at -20˚C for 24 h. Protein in the medium was precipitated by centrifugation at 12,000 x g for 20 min at 4˚C and the pellet was reconstituted into the same volume (~50 µl) of M-PER as that of the cell extracts. The concentration of protein extracts from the cell lysates and the tissue culture medium was determined using a Bio-Rad protein assay (cat. no. 500-0006JA; Bio-Rad Laboratories, Inc., Hercules, CA, USA), and the same volume of protein extract (10 µg protein extract) obtained from both samples was used for western blot analysis. Western blot analysis was performed using 10 µg of protein extracts and the procedures described previously (5). Briefly, extracted protein samples were separated by 4-20% polyacrylamide gel electrophoresis and transferred onto polyvinylidene difluoride membranes (GE Healthcare Life Sciences, Chalfont, UK). After blocking in 10% skim milk, the membranes were incubated with primary antibodies at a 1:500 dilution at 4˚C overnight. The membranes were then washed with PBS, incubated with secondary antibodies at a 1:1,000 dilution at room temperature for 1 h and rinsed with PBS. The antibodies used were as follows: Rabbit anti-REIC/Dkk-3 antibody raised in our laboratory (Okayama University of Science, Okayama, Japan), monoclonal mouse anti-tubulin antibody (cat. no. T5168; Sigma-Aldrich, St Louis, MO, USA), and horseradish peroxidase-linked anti-rabbit IgG secondary antibody (cat. no. 7074; Cell Signaling Technology, Inc.) or anti-mouse IgG secondary antibody (cat. no. 7076; Cell Signaling Technology, Inc.). Signals were visualized using the Enhanced Chemiluminescence Plus detection reagent (GE Healthcare Life Sciences).
Reverse transcription-polymerase chain reaction (RT-PCR) analysis. Total RNA was isolated from cultured NHKs using the SV Total RNA Isolation system (Promega Corporation, Madison, WI, USA) and pretreated with DNase I according to the manufacturer’s instructions. RT to generate cDNA was performed using the SuperScript II First-Strand Synthesis system (Thermo Fisher Scientific, Inc.). Total RNA was incubated with oligo dT primer, dNTP mixture and reverse transcriptase at 42˚C for 50 min. PCR analysis of human REIC/Dkk-3 mRNA expression levels was conducted using isolated RNA (10 µg) as described previously (11). Briefly, cDNA was amplified by ExTaq (cat. no. RR001; Takara Bio, Inc., Otsu, Japan) under the following conditions: Initial incubation at 94˚C for 4 min followed by 30 cycles at 94˚C for 30 sec, 55˚C for 30 sec, 72˚C for 30 sec, and then a final step at 72˚C for 5 min. GAPDH was used as an internal control. The primers used for PCR analysis were as follows: Human REIC/Dkk-3, forward 5’-CAGTTATACATCTGTTGAGACGAA-3’ and reverse 5’-AATCTTCAATCTACGCGGGACCTC-3’; GAPDH, forward 5'-GGGTGGTAAACATGGAAGTATGA-3’ and reverse 5’-TGCTAAGCAGTTGTTGTC-3’. The PCR products were examined for specificity via 1.5% agarose gel electrophoresis and visualized by ethidium bromide.

Results

Screening of factors regulating REIC/Dkk-3 expression in human keratinocytes. In order to identify factors that regulate REIC/Dkk-3 expression in normal human skin keratinocytes, NHK cells were treated with growth factors and cytokines that are reportedly involved in keratinocyte growth and differentiation, including EGF, TGF-β, TNF-α, IL-1F9, IL-6, IL-8 and Ca²⁺ (8,9). The protein expression levels were then determined by western blot analysis (12,13). As shown in Fig. 2, among these seven factors, only TNF-α was observed to downregulate REIC/Dkk-3 protein expression levels in NHKs. Downregulation of REIC/Dkk-3 by TNF-α was observed in both the cell extracts and tissue culture medium. IL-8 treatment appeared to increase REIC/Dkk-3 expression in the cell extract, but not in the culture medium.

Downregulation of REIC/Dkk-3 in skin tissues by TNF-α. Since the study identified that TNF-α treatment was able to reduce the expression of REIC/Dkk-3, its effect in tissue culture models of mouse skin were further investigated. Following in vitro incubation with 100 ng/ml TNF-α for 24 h, REIC/Dkk-3 expression in the mouse epidermis was downregulated when compared with that in the untreated epidermis tissue extracts (Fig. 3). Consistent with these observations, plucked hair follicles incubated with 100 ng/ml TNF-α exhibited a reduction in REIC/Dkk-3 expression compared with the untreated mouse hair follicles (Fig. 4).

Abrogation of TNF-α-mediated downregulation of REIC/Dkk-3 using a neutralizing anti-TNF-α antibody. In order to verify the effect of TNF-α treatment on the expression levels of REIC/Dkk-3, a competition assay was performed in NHKs using a specific neutralizing antibody against TNF-α. Immunocytochemical analysis demonstrated that treatment of NHKs with the anti-TNF-α antibody abrogated the TNF-α-mediated downregulation of REIC/Dkk-3 expression (Fig. 5). Similar results were obtained by western blot (Fig. 6A) and RT-qPCR analyses (Fig. 6B) of the REIC/Dkk-3 protein and mRNA expression levels in NHK cells, respectively.

Discussion

REIC/Dkk-3 is considered to be a tumor suppressor gene as its expression levels are reduced in numerous human malignancies (1). Previous studies have demonstrated that the REIC/Dkk-3 promoter region is frequently methylated in several malignant tissues, particularly in breast cancer tissues (14,15). However, Saeb-Parsy et al (16), reported that knockdown of the membrane type-1 matrix metalloproteinase induced upregulation of REIC/Dkk-3 expression in human
urothelial carcinoma cells. Thus, the mechanisms by which REIC/Dkk-3 expression is regulated in normal and cancer cells are not fully understood.

In the present study, a number of growth factors and cytokines were screened as potential regulators of REIC/Dkk-3 expression in normal skin keratinocytes. Among the seven factors screened, only TNF-α was observed to downregulate REIC/Dkk-3 expression in NHKs. The skin tissue culture model employed in the present study maintained a high level of REIC/Dkk-3 expression for 24 h. A reduction in REIC/Dkk-3 expression following TNF-α treatment was confirmed using this skin tissue culture model, as well as the incubated hair follicles, via immunohistochemistry analysis (Figs. 3 and 4). In addition, TNF-α-mediated downregulation of REIC/Dkk-3 in NHKs was abrogated by the treatment of cells with a neutralizing anti-TNF-α antibody.

TNF-α is a proinflammatory cytokine that is involved in the early-phase reaction of skin inflammation (12,17,18). TNF-α is expressed in pathological skin tissues, including hyperproliferative, ultraviolet-irradiated and wounded epidermis (19-21). TNF-α inhibitors have been used previously for the treatment of psoriasis and psoriatic arthritis (22,23). In a previous study, enhanced REIC/Dkk-3 expression was observed in hyperproliferative epidermal tissues, such as tissues in psoriasis and other inflammatory diseases (5). In addition, a downregulation of REIC/Dkk-3 expression was observed in skin tissues following
wound healing. These results suggest that REIC/Dkk-3 may serve a pivotal role in the regeneration of damaged skin tissues.

Following the exposure of skin keratinocytes, fibroblasts and other cells to TNF-α in vitro, keratinocytes exhibited an upregulation in mesenchymal markers and demonstrated an increased migration potential (24). These features are indicators of epithelial-mesenchymal transition (EMT), which is observed during wound healing. Treatment of dermal fibroblasts with TNF-α resulted in increased matrix metalloproteinase activity and enhanced cell migration capabilities in vitro (25). In addition, TNF-α induced the production of adhesion molecules and cytokines that mobilize immune cells into skin tissue (26). Cytokines produced by immune cells induced the proliferation and differentiation of keratinocytes, which led to skin tissue remodeling. Furthermore, stimulated keratinocytes produced cytokines to stimulate the surrounding keratinocytes and immune cells (27). The sequential stimulation of skin cells by secreted cytokines is an essential event during skin inflammation and skin tissue remodeling.

Lee et al (28), reported that activated human mesenchymal stem/stromal cells (hMSCs) secreted REIC/Dkk-3 to suppress the cell cycle progression in MDA-MB-231 breast cancer cells (28). In addition, it was demonstrated that REIC/Dkk-3 protein expression levels were upregulated in hMSCs following incubation of the cells with TNF-α (28). However, these previous observations contradict the results of the present study, where TNF-α was demonstrated to decrease REIC/Dkk-3 protein expression levels. Since these observations are contradictory, further studies are required to understand REIC/Dkk-3 regulation in different cell types.

In conclusion, the present study demonstrated that TNF-α reduced the expression of REIC/Dkk-3 in mouse skin keratinocytes and NHKs. This was confirmed by the observation that TNF-α reduced the expression of REIC/Dkk-3 in tissue culture models of mouse skin and hair. These results suggest that REIC/Dkk-3 may serve a pivotal role in skin inflammation and tissue remodeling.
