Abstract. Angiotensin II receptor blockers (ARBs) are widely used as hypertensive therapeutic agents. However, it has been reported that Telmisartan (a type of ARB) additionally activates peroxisome proliferator-activated receptor (PPAR)-γ. We previously reported that PPAR-γ ligand induced the growth arrest of renal cell carcinoma (RCC) cells through apoptosis, and that Telmisartan had the potential to inhibit prostate cancer cell growth through apoptosis. In this study, we evaluated the effects of Telmisartan and other ARBs on cell proliferation in an RCC cell line using normal proximal tubular endothelial cells (PRTECs) and the human RCC (Caki-1) cell line. The effects of Telmisartan as well as of other ARBs (Candesartan, Valsartan, Irbesartan and Losartan) on RCC cell growth were examined by MTT assay. Flow cytometry and Hoechst staining were used to determine whether or not the ARBs induced apoptosis. Telmisartan caused marked inhibition in RCC cells in a concentration- and time-dependent manner. Treatment with 100 μM of Telmisartan induced early apoptosis and DNA fragmentation in the RCC cells, but not in the PRTECs. None of the other ARBs had an effect on cell proliferation in the RCC cells or the PRTECs. Telmisartan may mediate potent antiproliferative effects against RCC cells through PPAR-γ. Thus, Telmisartan is a potential target for prevention and treatment in RCC.

Introduction
Recently, with increased routine medical check-ups and progress in diagnostic imaging techniques, there has been an increase in the number of cases of renal cell carcinoma (RCC) diagnosed. However, the causes of RCC remain unknown. Compared to many other types of cancer, RCC generally does not respond well to chemotherapy. Thus, surgery is currently the only therapeutic option.

Angiotensin II (AII) is known as a key biological peptide in the renin-angiotensin system, which regulates blood pressure and renal hemodynamics. ARB blockers (ARBs) are widely used as antihypertensive drugs (1). It is well known that angio genesis is essential for tumor progression and metastasis (2,3). Several studies have demonstrated that AII induces neovascularization and that ARBs inhibit vascular endothelial growth factor (VEGF) production (4,5). Benson et al reported a structural resemblance between Telmisartan (a type of ARB) and Pioglitazone, a peroxisome proliferator-activated receptor (PPAR)-γ ligand approved for the treatment of type 2 diabetes. They also reported that Telmisartan has PPAR-γ activation action (6).

PPARs are lipid-activated transcriptional factors that function as important regulators of lipid and glucose metabolism, adipocyte differentiation, and energy homeostasis. Several subtypes of PPAR (α, β and γ) have been found. PPAR-α and -γ mediate the action of hypolipidemic fibrates and anti diabetic thiazolidinediones. PPARs therefore play a role in metabolic conditions such as dyslipidemia and type 2 diabetes, leading to atherosclerosis development (7). They also have a regulatory role in inflammation. PPAR-γ provides a strong link between lipid metabolism and the regulation of gene transcription (8), acts in adipose tissue and promotes lipogenesis under ana bolic conditions. Recently, the PPAR receptor has also been implicated in inflammation and tumorigenesis. Significant evidence from many experimental systems suggests that PPAR-γ plays a key role in carcinogenesis.

Key words: Telmisartan, angiotensin II receptor blocker, peroxisome proliferator-activated receptor-γ, renal cell carcinoma, apoptosis
The ligands of PPAR-γ, which is up-regulated in malignant tissue, induce terminal differentiation in human breast and colon cancer cells (9,10) and inhibit the growth of human lung and gastric cancer cells (11,12). In addition, PPAR-γ ligands induce growth arrest through apoptosis in macrophage, fibroblast and endothelial cells (7,13,14).

We have previously reported that Telmisartan has the potential to inhibit the growth of prostate cancer cells through apoptosis (20). Consequently, in the present study we aimed to evaluate the inhibitory effect of Telmisartan on human RCC cells, and to determine whether or not it induces apoptosis in these cells. Our findings elucidate PPAR expression in urological cancer and indicate that the administration of PPAR-γ ligand may serve as a form of anticancer therapy (15-19).

Materials and methods

Reagents and materials. RPMI-1640 was purchased from Nissui Pharmaceutical Co. (Tokyo, Japan). Fetal bovine serum (FBS) and penicillin-streptomycin mixture were from Biowhittaker (Walkersville, MD, USA). Trypsin/EDTA was from Gibco BRL (Rockville, MD, USA). The ARB Losartan was from Toronto Research Chemicals Inc. (Canada). The ARB Losartan was from Champi Chemical (MI, USA).

Cell cultures. The human RCC (Caki-1) cell line and normal proximal tubular endothelial cells (PRTECs) were obtained from the Health Science Research Resources Bank (HSRRB, Osaka, Japan). Cells were grown in culture flasks (Nunc, Roskilde, Denmark) in RPMI-1640 supplemented with 10% FBS, 100 U/ml of penicillin and 100 μg/ml of streptomycin in a humidified 5% CO2 atmosphere at 37˚C. Media were changed every 3 days. When cells reached subconfluence, they were separated via trypsinization using trypsin/EDTA.

Cell-proliferation studies. Cells (~1.0x10⁴) were placed onto 8x8 mm diameter multichamber slides (Nunc) and treated with Telmisartan and other ARBs dissolved in ethanol, with a final ethanol concentration of <0.05%. Cell viability was measured on day 1 with a microplate reader using a modified 3-[4,5-dimethylthiazol-2-thiazolyl]-2,5-diphenyl-tetrazolium bromide (MTT) assay (WST-1 assay; Dojindo, Kumamoto, Japan), and presented as the percentage of control culture conditions.

Flow cytometry

Annexin V and propidium iodide staining. The effects of Telmisartan and the other ARBs (Candesartan, Valsartan, Irbesartan and Losartan) on the RCC cells and PRTECs were determined by dual staining with Annexin V-FITC and propidium iodide (PI) using the Annexin V-FITC Apoptosis Detection Kit 1 (BD Biosciences Pharmingen). Annexin V-FITC and PI were added to the cellular suspension according to the manufacturer’s instructions, and a sample fluorescence of 1.0x10⁴ cells was analyzed by flow cytometry conducted with FACScan (Becton-Dickinson, Germany), and presented as the percentage of control culture conditions.

Detection of apoptosis. DNA chromatin morphology was assessed using Hoechst staining. RCCs and PRTECs were incubated with 100 μM Telmisartan and other ARBs for 24 h. Cells were washed by RPMI-1640 and labeled with 8 mg/ml of Hoechst 33342 (Sigma-Aldrich Japan K.K., Tokyo, Japan)
for 10 min. PI (Sigma-Aldrich Japan K.K.) was added for a final concentration of 10 mg/ml, and the cells were examined by fluorescence microscopy.

Results

Telmisartan-induced growth inhibition in RCC cells by MTT.

To investigate the effects of Telmisartan and other ARBs on RCC cell proliferation, we analyzed cell viability in vitro using the MTT assay. As shown in Fig. 1A, Telmisartan induced a reduction in cell viability with the half-maximal concentration of growth inhibition of RCC cells (range 25-100 μM). However, Telmisartan and the other ARBs had no effect on PRTEC proliferation (Fig. 1B). Furthermore, cell counts on days 1, 2 and 3 clearly indicate a marked inhibition of cell proliferation with 100 μM of Telmisartan (Fig. 1C). Telmisartan therefore halted the growth of RCC cells.

Telmisartan-induced apoptosis by flow cytometry. Flow cytometry was used to evaluate whether cell death induced by Telmisartan and the other ARBs was achieved through apoptosis. As shown in Fig. 2, treatment with 100 μM of Telmisartan induced early apoptosis in almost the total percentage of RCC cells (Fig. 2A), while treatment with the same amount of Telmisartan antagonist in PRTECs had no effect (Fig. 2B).
Additionally, treatment with 100 μM Telmisartan induced DNA fragmentation in the RCC cells (Fig. 2A), but not in the PRTECs (Fig. 2B). The other ARBs did not induce DNA fragmentation in the RCCs or PRTECs (data not shown).

**Effect of Telmisartan on the induction of apoptosis in RCC cells.** To evaluate whether or not cell death induced by Telmisartan was caused by apoptosis, we evaluated the chromatin morphology of RCC cells and PRTECs using Hoechst staining. RCCs treated with Telmisartan exhibited significant chromatin condensation, cellular shrinkage, small membrane-bound (apoptotic) bodies and cytoplasmic condensation. These cellular changes were typically redundant characteristics of apoptosis (Fig. 3A). Untreated RCC cell lines maintained normal chromatin patterns and cell size (Fig. 3B).

On the other hand, PRTECs treated with Telmisartan did not exhibit significant chromatin condensation, cellular shrinkage, small membrane-bound bodies (apoptotic bodies) or cytoplasmic condensation (Fig. 3C). Untreated PRTECs maintained normal chromatin patterns and cell size (Fig. 3D).

Furthermore, RCC cells and PRTECs treated with other ARBs did not exhibit significant chromatin condensation, cellular shrinkage, small membrane-bound (apoptotic) bodies or cytoplasmic condensation (data not shown).

**Discussion**

Anticancer and antiangiogenic effects of angiotensin II receptor blockers. ARBs have been synthesized and available for the treatment of hypertension since the 1990s (21,22). AII has been known to promote tumor growth and angiogenesis, while ARBs have been considered a noteworthy anticancer and antiangiogenic therapeutic option (23).

In previous years, some tumor cells, such as melanoma, pancreatic cancer (24), renal cancer (25,26), breast cancer (27), bladder tumor (28) and prostate cancer (29), were reported to express the AII receptor (24,25,28-31). Several studies have investigated the antitumor effect of ARBs throughout antiangiogenesis. Kosugi et al reported that Candesartan (an ARB) prevented the pulmonary metastasis of renal cancer and bladder tumors by inhibiting tumor angiogenesis through the suppression of VEGF in a xenograft model (28). In prostate cancer, some investigators reported that Candesartan inhibited the production of VEGF, one of the most potent and specific angiogenic factors, and decreased the prostate cancer (29,32). Kosaka et al reported that a specific ARB suppressed VEGF production, resulting in reduced tumor angiogenesis and a slower progression of prostate cancer in a tumor xenograft model (29). Uemura et al reported that the clinical use of
Candesartan in prostate cancer patients with hypertension resulted in a reduction of prostate-specific antigen, while patient performance status improved (32). However, they also reported that Candesartan had no effect on tumor growth in vitro, and did not detect apoptosis. Based on their in vitro and in vivo experiments, they suggested that the antitumor effect of ARB was not due to direct toxicity or apoptotic induction, but was rather an antiangiogenic effect (28,29).

The results of the present study indicate that Candesartan and other ARBs (with the exception of Telmisartan) did not induce a reduction in cell viability and early apoptosis in RCC cells. Telmisartan alone induced a reduction in cell viability, with a half-maximal concentration of growth inhibition, early apoptosis and the DNA fragmentation of the RCC cells.

Telmisartan is a partial agonist of peroxisome proliferator-activated receptor-γ. Benson et al reported a structural resemblance between Telmisartan and Pioglitazone, a PPAR-γ ligand approved for the treatment of type 2 diabetes. They found that Telmisartan blocks the AII receptor, activating PPAR-γ. Telmisartan functioned as a moderately potent selective PPAR-γ and also as a partial agonist, activating the receptor to 25-30% of the maximum level achieved by the full agonists pioglitazone and resiglitazone (6).

Anticancer effects of peroxisome proliferator-activated receptor-γ. PPARs are members of the nuclear receptor superfamily of ligand-activated transcriptional factors, such as steroids, thyroid hormone, vitamin D, and retinoic acid. PPAR binds to the peroxisome proliferator response element as a heterodimer with the retinoic receptor in the regulation of PPAR target genes. PPARs are considered to be important immunomodulatory factors, as well as fatty acid regulators. They modulate these activities in different immune cell types, such as monocytes/macrophages, lymphocytes and endothelial cells (33).

PPAR-γ is expressed at high levels in adipose tissue, where it acts as a critical regulator of adipocyte differentiation. It is also expressed in the immune system, the spleen, monocyte bone-marrow precursors and helper T-cell clones, as well as in chondrocytes, synovial and bone tissues. Recent data indicate that the PPAR-γ ligand leads to the inhibition of phorbol ester-induced nitric oxide and macrophage-derived cytokines, such as tumor necrosis factor-α, interleukin-1β and -6, chemokines, and adhesion molecules. It accomplishes this inhibition in part by antagonizing the activities of transcriptional factors (11). Thiazolidinedione, a new class of antidiabetic as a specific ligand for PPAR-γ, and retinoic receptor agonists, have been evidenced to regulate the differentiation of cancer cells (34). Moreover, nuclear-acting prostanoids, including 15-deoxy-D12,14-prostaglandin J2 (15-dPGJ2), are potent activators of the PPAR-γ receptor isoform (35,36). 15-Deoxy-D12,14-prostaglandin J2 induces apoptosis in macrophages, endothelial cells and choriocarcinoma cells (7,14,37), as well as thiazolidinedione-induced fibroblast apoptosis (8).

We previously reported that PPAR-γ was strongly expressed in RCC tissues. The extent and intensity of PPAR-γ expression was greater in normal kidney tissues than in RCC tissues. PPAR-γ expression was also stronger in high-grade than in low-grade carcinoma. PPAR-γ ligand strongly induced early apoptosis in RCC cells, as indicated by flow cytometry and Hoechst staining (15). In this study, only Telmisartan had a direct toxicity throughout apoptosis. Thus, it may mediate potent antiproliferative effects against RCC cells through PPAR-γ. However, the dose required for this effect was not clinically achievable in the current study. Further studies are needed to extend the application of Telmisartan to a clinical trial of treatment for RCC.
