Abstract. The enhancement of glucose metabolism in neoplastic cells is mediated by the overexpression of key glycolytic enzymes and glucose transporters (GLUTs). In particular, an increased expression of hypoxia-related GLUT1 and GLUT3 has been found in a variety of malignancies. The aim of this study was to examine the expression levels of GLUT1 and GLUT3 in benign and malignant thyroid tumors, as well as in non-neoplastic lesions. Analysis of the mRNA expression levels of solute carrier family 2, member 1 (SLC2A1) and solute carrier family 2, member 3 (SLC2A3) (genes coding GLUT1 and GLUT3, respectively) was performed by the real-time PCR method with fluorescent probes. GLUT1 and GLUT3 protein expression levels were determined in thyroid specimens by immunodetection after separation of proteins on 10% polyacrylamide slab gels and electrotransfer onto Immobilon-P membranes. The majority of papillary carcinoma samples showed a higher expression of GLUT1 and GLUT3 in comparison with follicular carcinoma cases and non-neoplastic thyroid lesions. A tendency towards an increased expression of GLUT1 and GLUT3 was observed in papillary carcinoma cases with more advanced disease stages. Moreover, a significant correlation was noted between the hypoxia-related GLUT1 and GLUT3 expression determined by both methods. In conclusion, our findings suggest that GLUT1 and GLUT3 play an important role in the pathology of thyroid glands.

Introduction

Since the early observation by Otto Warburg, it has been well known that tumor cells are characterized by an increased requirement for energy metabolism. Additionally, these cells, have a reduced ability to use mitochondrial oxidation and favor the conversion of pyruvate into lactate, despite the availability of oxygen. To compensate the inefficient extraction of energy from glucose, malignant cells have an at least a 20- to 30-fold higher rate of glycolysis than normal cells. This enhancement of glycolytic metabolism requires an increased rate of glucose uptake into tumor cells. The upregulation of glucose transport across the plasma membrane is mediated by a family of facilitative glucose transporter proteins (GLUTs), which differ regarding their tissue-specific distribution and affinity for glucose (1,2). These structurally-related carriers contain 12 transmembrane spanning α-helix domains with both the amino and carboxyl termini exposed on the cytoplasmic side of the plasma membrane (3).

The deregulation of glucose metabolism in cancer cells is predominantly mediated by oxygen-related transcription factors, such as the hypoxia-inducible factor 1 (HIF-1). HIF-1 induces a number of genes encoding glycolytic enzymes, erythropoietin, the tumor-associated carbonic anhydrases (CAs), CAIX and CAXII, vascular endothelial growth factor (VEGF), as well as the facilitative GLUT isoforms 1 and 3 (GLUT1 and GLUT3). Hypoxia-related GLUTs are characterized by low Km values and high affinity for glucose as compared to other members of the GLUT family. GLUT1 is mostly expressed in erythrocytes, placental cells and endothelial cells of the blood-brain barrier, whereas GLUT3 is found mainly in the brain, placenta and other cell-types, with an intense requirement for glucose (4,5). Previous studies have provided evidence of human malignancies expressing a higher level of GLUT1 and GLUT3 in comparison with normal cells. The overexpression of hypoxia-related GLUTs has been demonstrated in a variety of tumors, including lung, endometrium, breast, liver, kidney, head and neck, colon and oral squamous cell carcinomas (6-13). In general, the overexpression of GLUT1 and GLUT3 in different tumor types correlates with specific clinicopathological characteristics, malignant potential and poor prognosis. It has been suggested that the expression pattern of both transporters may be used as a prognostic factor of malignancy and progression, possibly assisting in the selection of patients requiring more aggressive therapy.

Some of the contradictory results concerning the level of GLUT1 and GLUT3 expression in thyroid lesions can be found in the literature. Therefore, the aim of this study was to clarify whether there is any difference in the expression of GLUT1 and GLUT3 between benign and malignant neoplasms and non-neoplastic thyroid lesions.

Materials and methods

Patients and samples. The analyzed specimens were obtained from the Department of General and Oncological Surgery of the Medical University of Łódź. The material comprised samples from 73 patients, who underwent surgical resection due to nodular thyroid diseases. Thyroid specimens from patients were rapidly frozen and stored at -80°C until needed. The histological diagnosis report of each patient was obtained from an experienced pathologist. Patient characteristics and specimens are presented in Table I. Typing and staging of tumors were carried out according to the system accepted by the International Union Against Cancer (UICC, 2010).

Isolation of cytoplasmic fraction. Pathological thyroid specimens were homogenized using a Potter's homogenizer in 10 volumes of ice-cold sucrose buffer (0.25 M sucrose, 5 mM MgCl₂, 0.8 mM KH₂PO₄, pH 6.7) with 1 mM phenylmethylsulfonyl fluoride (PMSF) to inhibit protease activity. The efficiency of homogenization was monitored by phase-contrast light microscopy. The supernatants obtained after homogenate centrifugation at 800 x g at 4°C for 10 min (sedimentation of nuclei) were considered as cytoplasmic fractions including cellular membranes and saved for further analysis.

RNA isolation and cDNA synthesis. Total RNA was isolated from frozen specimens by using Fenzol reagent (A&A Biotechnology, Gdynia, Poland). The RNA quality was confirmed by electrophoresis on a 1.2% agarose gel with ethidium bromide staining and the 18S and 28S rRNA bands were visualized under ultraviolet light. The yields were quantified spectrophotometrically. RNA samples with a 260/280 nm ratio in the range 1.8-2.0 were saved for further analysis. cDNA was then synthesized from 2 µg of total RNA using a RevertAid™ First-Strand cDNA Synthesis kit (Fermentas Inc., Vilnius, Lithuania), following the manufacturer's instructions.

Quantitative real-time PCR. Quantitative real-time PCR with commercially available primers and fluorescent probes (TaqMan® Gene Expression Assay; Applied Biosystems™, Foster City, CA, USA) was employed to detect the expression of the target genes [solute carrier family 2 member 1 (SLC2A1) and solute carrier family 2 member 3 (SLC2A3)] encoding GLUT1 and GLUT3 in different types of thyroid lesions. The GAPDH gene was used as the internal control. The assay numbers for these genes were as follows: Hs00892681_m1 and Hs00359840_m1.

Each PCR reaction was performed in a 10 µl volume that included 5 µl of 2X TaqMan Universal PCR MasterMix (Applied Biosystems™), 4.5 µl of water-diluted cDNA template and 0.5 µl of TaqMan® Gene Expression assay consisting of a pair of unlabeled PCR primers and a TaqMan FAM™ fluorescent probe. The RT-qPCR reaction was carried out using the Mastercycler ep realplex (Eppendorf) under the following conditions: denaturation for 10 min at 95°C followed by 50 cycles of 15 sec at 95°C, 1 min annealing and extension at 60°C.

The 2^−ΔΔCt (Cgene–Cctl) method was used to estimate the relative gene expression levels in the analyzed samples. The 2^−ΔΔCt values were re-calculated into relative copy number values (number of SLC2A1 or SLC2A3 mRNA copies per 1,000 copies of GAPDH mRNA).

Western blot analysis. The protein samples were mixed with solubilizing buffer. Samples were not heated in a boiling water bath before SDS-PAGE but incubated for 15 min at room temperature in order to avoid GLUT protein aggregation. Denatured proteins of different types of thyroid lesions (30 µg protein/lane) were resolved by electrophoresis on a 10% polyacrylamide slab gel with 0.1% SDS according to Laemmli (14) and electrotransferred onto Immobilon-P transfer membranes (Millipore, Bedford, MA, USA) by western blotting in Towbin's buffer (15). The quality of transfer was verified by Ponceau S staining before blocking the membrane. Then, the blots were incubated for 2 h at room temperature with the rabbit anti-human GLUT1 polyclonal antibodies in a 1:1000 dilution (Abcam®, Cambridge, UK) or mouse anti-human GLUT3 monoclonal antibodies in a 1:500 dilution, (Santa Cruz Biotechnology Inc., Santa Cruz, CA, USA). Blots were washed 3 times with TBS-T (0.1% Tween-20 in Tris-buffered saline, TBS) for 15 min, and were incubated for 1 h at room temperature with horseradish peroxidase-labeled goat anti-rabbit or goat anti-mouse IgG antibodies, which were added at a dilution of 1:5000, (Santa Cruz Biotechnology Inc.). After extensive washing with TBS-T, the proteins were visualized on X-ray film by the enhanced chemiluminescence method. To confirm that the same amounts of proteins were loaded into each lane, the standard silver staining method was used for total protein identification on the gels (16). Gel-Pro Analyzer software version 3.0 (Media Cybernetics Inc., Bethesda, MD, USA) was used for densitometry analysis of the protein bands.

Statistical analysis. Statistical evaluation was performed using STATISTICA version 9.0 (StatSoft, Krakow, Poland). The non-parametric Mann-Whitney U test and Spearman rank analysis were applied. A p-value <0.05 was considered to indicate a statistically significant difference.

Results

Expression of GLUT1 and GLUT3 mRNA. mRNA levels of GLUT1 and GLUT3 were determined by real-time PCR in different thyroid specimens, such as non-neoplastic lesions i.e. nodular goiters (NGs) follicular adenomas (FAs), papillary carcinomas (PCs) and follicular carcinomas (FCs). The results of GLUT1 and GLUT3 gene expression in each type of thyroid lesions are presented in Table II and graphed in Fig. 1. The results indicate that SLC2A1 gene (GLUT1) had a significantly higher expression in PCs than in non-neoplastic lesions (p<0.05) (Table II and Fig. 1A). In addition, a lower level of GLUT1 mRNA was observed in FCs in comparison with non-neoplastic, benign lesions and PCs (p<0.01). No statistically significant differences were found in GLUT1 mRNA levels between benign and non-neoplastic lesions. There were similar findings regarding the hypoxia-related SLC2A3 gene (GLUT3). The data showed a higher expression level of GLUT3 mRNA in PC cases than in FCs (p<0.01) and non-neoplastic lesions (p<0.05) (Table II and Fig. 1B). Moreover, in the PC group, a tendency towards an increased expression of GLUT1 and GLUT3 mRNA with more advanced disease.
stages was found (Fig. 1C and D). No statistically significant differences were noted in the expression of both genes in PC cases with or without metastasis to lymph nodes (Fig. 1E and F). A correlation was found between GLUT1 and GLUT3 mRNA expression (Spearman’s rank analysis, p<0.001).

GLUT1 and GLUT3 protein level. The expression of GLUT1 protein with the expected molecular masses in the range of 41-55 kDa (corresponding to its heterogeneously glycosylated species) was detected in all types of thyroid lesions (Fig. 2A). However, there were some differences in the level of GLUT1 expression between the various groups of thyroid lesions (Table II and Fig. 3A). The majority of the PC samples showed a higher immunoreactivity for GLUT1 in comparison with the non-neoplastic thyroid lesions (p<0.05) (Fig. 2A). The relative GLUT1 protein level was low in FCs compared to other types of lesions (p<0.01). A tendency towards an increased expression of GLUT1 was observed in the PC group with an elevated tumor stage (Fig. 3C). No obvious differences were noted regarding other histological features, such as the lymph node status (Fig. 3E).

The results of the GLUT3 expression in thyroid lesions determined by western blot analysis are shown in Fig. 2B. The highest expression of GLUT3 was associated with PCs as opposed to low GLUT3 immunoreactivity in FCs (p<0.01) and non-neoplastic lesions (p<0.05) (Table II and Fig. 3B). No statistically significant differences were found in the GLUT3 protein level between non-neoplastic lesions (NGs) and the benign neoplasm group (FAs). Moreover, as observed in the GLUT1 expression patterns, the data showed a significantly higher GLUT3 protein level in stage IV than in stage I of PC (Fig. 3D). There were no statistically significant differences in GLUT3 expression in PC cases with or without metastasis to lymph nodes (Fig. 3F). There was a noted correlation between the GLUT1 and GLUT3 protein expression (Spearman’s rank analysis, p<0.05), whereas a significant correlation was noted between GLUT1 and GLUT3 expression levels determined by real-time PCR and those obtained by western blot analysis (Spearman’s test analysis, p<0.01 and p<0.05, respectively).

**Discussion**

It is widely accepted that malignant cells enhance glucose metabolism. Such a high rate of glucose metabolism cannot be sustained without the upregulation of facilitative GLUTs (1,2). In this study, using real-time PCR and western blot analysis, we investigated whether there is any difference in the expression of hypoxia-related GLUT1 and GLUT3 between benign and malignant neoplasms, as well as non-neoplastic thyroid lesions.
To date, GLUT1 expression in thyroid malignancies has mainly been investigated immunohistochemically. There are, however, some discrepancies between the results of these studies. Chandan et al (17) described negative GLUT1 staining in all 15 (100%) examined cases with an unequivocal cytological diagnosis of PC. Kim et al (18) detected a positive expression of GLUT1 only in anaplastic carcinomas, which correlated with the impairment of p53 and p63 upregulation. Haber et al (19) reported a positive immunohistochemical expression of GLUT1 in both well- and poorly-differentiated thyroid carcinomas.

Our results, obtained by western blot analysis, showed a higher intensity of bands corresponding to GLUT1 in the majority of PC samples in comparison with non-neoplastic thyroid lesions. We also observed that the expression level of GLUT1 was significantly higher in PC than in FC cases, which is in agreement with the data previously reported (19-21). In our study on SLC2A1 (GLUT1) gene expression comparable findings were obtained.

There is little information in the literature regarding the GLUT3 expression in thyroid cancer. Ciampi et al (22) reported the most prevalent GLUT3 mRNA expression in well-differentiated thyroid papillary (NPA) and follicular (WRO) carcinoma cell lines. Another study showed slightly higher GLUT3 mRNA expression levels in thyroid cancer cells than in normal ones, although the results were not statistically significant (23). Contrary to the immunohistochemical analysis (21), we detected GLUT3 isofrom expression both on the protein and mRNA levels. Our results revealed a higher level of GLUT1 in papillary than in FCs and non-neoplastic thyroid lesions. Moreover, we observed a tendency towards an expression of GLUT1 only in anaplastic carcinomas, which correlated with the impairment of p53 and p63 upregulation. Haber et al (19) reported a positive immunohistochemical expression of GLUT1 in both well- and poorly-differentiated thyroid carcinomas.

Our results, obtained by western blot analysis, showed a higher intensity of bands corresponding to GLUT1 in the majority of PC samples in comparison with non-neoplastic thyroid lesions. We also observed that the expression level of GLUT1 was significantly higher in PC than in FC cases, which is in agreement with the data previously reported (19-21). In our study on SLC2A1 (GLUT1) gene expression comparable findings were obtained.

There is little information in the literature regarding the GLUT3 expression in thyroid cancer. Ciampi et al (22) reported the most prevalent GLUT3 mRNA expression in well-differentiated thyroid papillary (NPA) and follicular (WRO) carcinoma cell lines. Another study showed slightly higher GLUT3 mRNA expression levels in thyroid cancer cells than in normal ones, although the results were not statistically significant (23). Contrary to the immunohistochemical analysis (21), we detected GLUT3 isofrom expression both on the protein and mRNA levels. Our results revealed a higher level of GLUT1 in papillary than in FCs and non-neoplastic thyroid lesions. Moreover, we observed a tendency towards an
increased expression of GLUT1 and GLUT3 in the PC group with a more advanced tumor stage.

The results of the present study suggest that the differences in GLUT1 and GLUT3 expression levels are associated with the histological type of thyroid carcinomas. Both hypoxia-related GLUT1 and 3 are involved in the progression of papillary thyroid carcinomas and may be added to a panel of biological thyroid carcinoma markers. For the first time in the literature we observed a close correlation between the overexpression of GLUT1 and GLUT3 proteins and the high levels of GLUT1 and GLUT3 mRNA in the same thyroid cancer specimens. However, in some neoplasm cases we were not able to detect the GLUT1 or GLUT3 positive band and the mRNA level was very low. A hypothesis that provides an acceptable explanation for these findings is that the expression of hypoxia-related GLUTs is further influenced by the microenvironment of tumor cells. Some authors have observed the most prominent GLUT1 expression around the necrotic areas or the hypoxic regions of tumors (23,24). The study of Tomes et al (25) on breast carcinomas showed that necrosis was usually associated with hypoxia and the co-expression of HIF1, CAIX and GLUT1. They also found that in cases of tumor epithelium without associated necrosis, GLUT1 was present at a low frequency. A similar phenomenon has been reported in thyroid malignancies, which usually show extensive GLUT1 immunostaining in the center of tumor cell groups or in perinecrotic areas (20,21). In our study, we observed a correlation between GLUT1 and GLUT3 expression levels determined by both real-time PCR and western blot analysis. Our results suggest that hypoxia-related GLUTs in the thyroid may be regulated by common factors.

By contrast, the lack of hypoxia-related GLUTs in some examined samples suggests the possibility that other GLUT isoforms may be expressed. The expression of GLUT2, GLUT5 and GLUT10 has been reported in thyroid tissue (21,26).

In conclusion, we presume that hypoxia-related GLUTs may play an important role in the glucose metabolism of thyroid neoplasms. Further investigations are required to clarify the exact regulation of hypoxia-related GLUT1 and GLUT3 in thyroid cancer cells.
