Abstract. Numerous studies have suggested that interleukin 11 (IL-11) has roles in human gastric, prostate and bone cancer and endometrial carcinoma. Hence, we evaluated the expression of IL-11 in bladder cancer and the correlation of IL-11 levels and clinicopathological features. The expression of IL-11 in primary human bladder cell culture, human bladder cancer cell lines, transitional cell carcinoma (TCC) and non-cancerous bladder tissues (NATs) were analyzed by western blotting. Enzyme-linked immunosorbent assay (ELISA) for urinary IL-11 was performed to compare the IL-11 levels in healthy subjects and subjects diagnosed with bladder cancer. Our study suggested that the expression of IL-11 in human bladder cancer cell lines and TCC was down-regulated compared with primary human bladder cell culture and matched NATs. We also demonstrated reduced urinary levels of IL-11 in subjects with bladder cancer compared with healthy subjects. Furthermore, we revealed that the levels of IL-11 were associated with tumor grade and stage. The results suggested that reduced levels of IL-11 may play an important role in the carcinogenesis and progression of TCC. They also indicated that IL-11 may be a promising predictor for prognosis of TCC.

Introduction

Bladder cancer is one of the most common malignancies worldwide. In the western world it is the seventh most common malignancy among males, following lung, prostate, colon, stomach, liver and esophagus cancer, and is the second most common cause of mortality among genitourinary tumors. It was estimated that in the western world there would be 70,530 new cases and 14,680 deaths due to bladder cancer in 2010 (1-3). Bladder cancer is compromised of tumors that exhibit a wide spectrum of clinical behavior. Approximately 90% of bladder cancers are transitional cell carcinoma (TCC), whereas 5% are squamous cell carcinomas and 1-2% are adenocarcinomas (3,4). The most common form of the disease, which accounts for 70-80% of cases, is usually low-grade, multifocal, superficial and papillary. The less common, muscle invasive form of the disease accounts for 20% of bladder cancer cases (5). Although major work has been focused on tackling the problem of bladder cancer, our understanding of the molecular and cellular mechanisms that underlie cancer carcinogenesis and progression remains poor.

Patients with low-grade, non-invasive bladder cancer are managed with simple resection and fulguration of the tumor and selective intravesical chemotherapy (6,7). Patients with high-grade non-invasive or muscle invasive cancer are treated with more aggressive therapies, such as immunotherapy for non-muscle invasive lesions and radical cystectomy, chemotherapy and occasionally radiation therapy for muscle invasive disease (7,8). The standard of care, while effective, is associated with a considerable side-effect profile, and >30% of patients fail to respond to treatment or suffer recurrent disease within 5 years (9). Therefore, patients with bladder cancer need to be monitored for cancer recurrence or progression. It is also important to predict the prognosis of the patients to enable more active treatment in order to prolong their lives.

Interleukin (IL)-6-like cytokines are characterized by a common signal chain (gp130) in the receptor complex. This family is comprised of polypeptides with a molecular weight of 20 kDa, and includes IL-6, IL-11, IL-31, ciliary neurotrophic factor (CNTF), leukemia inhibitory factor (LIF), oncostatin-M (OSM), cardiotropin-1 (CT-1), cardiotropin-like cytokine (CLC) and neuropaetotic hormone (NPN). Among these IL-6-like cytokines, IL-11 was first cloned from the primates stromal cell line PU-34 and is expressed by a variety of tissues, such as gut, brain, spinal cord neurons and testes, and hence may have a physiological role in these organs (10,11). IL-11 has been mapped in humans to chromosome 19 at the q13.3-q13.4 locus (12). The genes spans 7 kb and consists of 5 exons and 4 introns (13). Numerous studies have suggested that IL-11 has roles in human gastric, prostate and bone cancer, and endometrial carcinoma (14). The uterine washing level of

Key words: interleukin-11, bladder cancer, prognosis
IL-11 has been found to be elevated and to play a complex role in the progression of endometrial carcinoma. IL-11 was also demonstrated to be upregulated and associated with clinicopathological features in gastric cancer (15). However, no studies have investigated the expression of IL-11 in bladder cancer and the correlation of IL-11 level and clinicopathological features.

In this study, the levels of IL-11 were shown to be downregulated in bladder cancer cell lines and TCC compared with primary human bladder cell culture and NATs. We also showed reduced urinary levels of IL-11 in subjects with TCC compared with healthy subjects. Furthermore, we revealed that the levels of IL-11 were associated with tumor grade and stage. These results suggest that reduced levels of IL-11 may play an important role in the carcinogenesis and progression of TCC. They also indicate that IL-11 may be a promising predictor for the prognosis of TCC.

Materials and methods

Patients and clinical specimens. Tissue specimens used in this study were collected at the Yancheng City No. 1 People's Hospital. Tissues were obtained after patients provided written informed consent under a general tissue collection protocol approved by the faculty/institutional research committee. Urine samples were obtained from individuals with no previous history of urothelial carcinoma, gross hematuria, active urinary tract infection or urolithiasis and individuals with newly diagnosed TCC. Tissues were snap-frozen in liquid nitrogen. The urine samples were stored at -80°C.

Cells and culture conditions. The human bladder cancer cell lines T24, J82, HT-1376, 253J, RT4, TCC-SUP and primary human bladder cell culture were kindly donated by the Jiangsu Province Hospital, the First Affiliated Hospital of Nanjing Medical University. The cells, but not the primary human bladder cell culture, were cultured in RPMI-1640 medium supplemented with 10% heat-inactivated fetal bovine serum, 100 U/ml penicillin and 100 mg/l streptomycin at 37°C in a humidified atmosphere containing 5% CO2. The primary human bladder cell culture was cultured in Eagle’s minimum essential medium (EMEM) supplemented with 10% heat-inactivated fetal bovine serum, 100 U/ml penicillin, 100 mg/l streptomycin, 0.56 µg/ml amphotericin B, 1.0 U/ml insulin and 10 mM HEPES at 37°C in a humidified atmosphere containing 5% CO2. Cells were subcultured every 2 days using trypsin/EDTA solution (saline containing 0.05% trypsin, 0.01 M sodium phosphate and 0.53 µM EDTA, pH 7.4).

Enzyme-linked immunosorbent assay (ELISA) for urinary IL-11. The quantitative determination of urinary concentrations of IL-11 was performed using ELISA kits (Quantikine; R&D Systems, Abingdon, UK). All assays were conducted according to the manufacturer’s instructions. Calibration curves were prepared using purified standards. Curve fitting was accomplished by either linear or four-parameter logistic regression according to the manufacturer’s instructions.

Western blotting. Primary antibodies used in this study, including IL-11 and β-actin, were products of Bioworld Technology (Louis Park, MN, USA). Total protein of tissue specimens and cells were prepared using RIPA lysis buffer. The protein concentration in the resulting lysate was determined using the bicinchoninic acid assay. Equal amounts of protein were loaded onto SDS-PAGE and transferred to a PVDF membrane. After blocking with 5% skimmed milk in TBST, the membranes were incubated overnight with appropriately diluted primary antibody at 4°C. They were then washed and incubated with the corresponding hors eradish peroxidase-conjugated secondary antibody at a 1:2,000 dilution in TBST. The blot was developed with ECL solution (Pierce Biotechnology, Inc., Rockford, IL, USA) and images were obtained using the FluorChem imaging system (Alpha Innotech, CA, USA). The intensity of each spot was read and analyzed with AlphaEaseFC software.

Statistical analysis. Data are presented as the mean ± standard deviation (SD) and compared using the Student’s t-test in Stata 10.0 (College Station, TX, USA). A double-tailed P-value <0.05 was considered to indicate a statistically significant difference.

Results

Urinary levels of IL-11 in healthy subjects and subjects with TCC. First, we examined the expression of IL-11 in 27 healthy subjects and 32 subjects with TCC by using ELISA. The urinary IL-11 levels in healthy subjects were 9.44±2.09 pg/ml urine compared with 4.85±2.60 pg/ml urine in subjects diagnosed with TCC (Fig. 1). The statistical analysis revealed that the urinary levels in subjects diagnosed with TCC were lower compared with healthy subjects (P<0.05).

Expression of IL-11 in TCC, NATs, primary human bladder cell culture and bladder cancer cell lines. We also examined the expression of IL-11 in primary human bladder cell culture and bladder cancer cell lines using western blotting. In the present study, we used seven types of bladder cancer cell
The results showed that IL-11 levels in bladder cancer cell lines were significantly lower compared with primary human bladder cell culture. We then compared the expression of IL-11 in TCC and NATs. We used 22 paired samples of TCC and NATs. According to the results, IL-11 protein levels in TCC were significantly downregulated compared with NAT samples (Fig. 2). These results demonstrated that IL-11 was downregulated in human bladder cancer cell lines and TCC compared with primary human bladder cell culture and matched NATs.

Correlation between IL-11 level and clinicopathological features in patients with TCC. The expression of IL-11 is associated with clinicopathological features in gastric and endometrial cancer (16,17). Therefore, we examined whether the level of IL-11 was associated with the tumor grade and stage. According to the results, superficial bladder cancer (Tis, Ta and T1) had a high level of IL-11 compared with invasive bladder cancer (T2, T3 and T4); low-grade bladder cancer also had a high level of IL-11 compared with high-grade bladder cancer. The statistical analysis showed that there was a significant association between the IL-11 expression level and the tumor grade and stage (Fig. 3).

Figure 3. Correlation between IL-11 level and clinicopathological features in patients with bladder cancer. The relative IL-11 levels of patients with TCC have significant correlation with (A) tumor grade and (B) tumor stage. TCC, transitional cell carcinoma; IL, interleukin.
Discussion

In this study, we presented definitive evidence that IL-11 was downregulated in human bladder cancer cell lines, TCC and urine samples. Our data also showed that there was a significant association between the IL-11 expression level and the tumor grade and stage. To the best of our knowledge, this is the first study demonstrating alterations in expression of IL-11 in human bladder cancer cell lines, TCC and urine samples.

IL-11 is a secreted pleiotropic cytokine first identified in an immortalized primate bone marrow stromal cell line (18). To date, IL-11 has been characterized most extensively as a cytokine with thymopoietic activity. It was also shown to have a number of additional biological activities, including stimulation of erythropoiesis (19), activation of megakaryocytes (20), modulation of neuronal phenotypes (21), regulation of macrophage precursors (22), promotion of stem cell development (23) and improved colonization of transplanted murine bone marrow cells (24). In addition, IL-11 is capable of stimulating B cell IgG production (25), and osteoblast-derivd IL-11 activates bone-resorbing osteoclasts with an associated decrease in de novo bone formation (26).

In several clinical and experimental studies, IL-11 exhibited anti-inflammatory activity (27,28). IL-11 mediates anti-inflammatory activities during chemotherapy-induced oral mucositis (29), acute intestinal ischemia (30) and in Clostridium difficile toxin A-associated intestinal toxicity (31). Directing IL-11 overexpression to the bronchial mucosa or airway epithelium in transgenic mice minimized hyperoxic lung injury and induced focal tissue fibrosis during the ensuing wound-healing response (32,33). These studies clearly show that IL-11 is capable of modulating the severity of inflammation-associated disease, however, the underlying mechanisms remain incompletely understood. In previous studies, IL-11 was demonstrated to act as an anti-inflammatory cytokine through directly reducing the number of macrophages and effectors at the site of inflammation. It has also been shown that IL-11 dampens the release of nitric oxide, TNF-α, IL-1β, and the immunomodulatory cytokines IL-12, IL-10, TGF-β and IL-6 (34).

There is substantial evidence that inflammation plays a direct role in bladder cancer carcinogenesis (35). To date, epidemiological data on urinary tract infections (UTIs) and bladder cancer risk have been conducted in developed countries where 89% or more of all tumors included in the studies were TCC. UTIs have been positively associated with the risk of bladder cancer in retrospective observational studies. Relative risks in these studies range between 1.4 and 16 for any history of urinary infection versus none. Similar associations have been observed for males and females (35).

Infection may induce tissue and DNA damage by activating of inflammatory cells, generating reactive oxygen and nitrogen species (36-38). Reactive oxygen and nitrogen species can directly produce single- or double-stranded DNA breaks, modify ribonucleic acid, lipids and proteins and modulate cell growth and tumor promotion by activating signals-translation pathways (37,39). At the site of inflammation, neutrophils, monocytes and macrophages generate a variety of reactive species, including superoxide anion, hydrogen peroxide and nitric oxide (37,39). Inducible nitric oxide synthase protein has been detected in transitional cell tumors of the bladder, but not in bladders of healthy patients (40). In this study, the results showed that IL-11 was downregulated in human bladder cancer cell lines, TCC and urine samples. The downregulation of IL-11 reduced its anti-inflammatory activity by reducing the impact on macrophages, effectors at the site of inflammation and nitric oxide. These results suggested that downregulation of IL-11 is a probable mechanism of bladder cancer carcinogenesis and progression. It may provide us with a promising method to prevent bladder cancer recurrence or progression.

A number of prognostic indicators of bladder cancer have been identified which serve as guides for clinical decision-making, recurrence or progression. Clinical staging and histopathological parameters are currently the most commonly used prognostic tools. Of these, the tumor, node and metastasis (TNM) staging system is a well-known prognostic tool used clinically (41). Various prognostic indices such as p53, p21 and Rb have also been devised by combining these factors (42). Although these prognostic indicators, to a certain extent, aid in the assessment of the severity of the disease, planning management and prediction of recurrence and prognosis, they are not always a good indicator of behavior in individual bladder cancer cases. Advances in molecular biology have provided new tools to make clinical decisions and predict prognosis in human bladder cancer. In this study, we demonstrated downregulation of IL-11 in human bladder cancer cell lines and TCC. It was associated with the finding that urinary levels in subjects diagnosed with TCC were lower compared with healthy subjects. Our results also indicated that invasive, high-grade bladder cancer had a decreased level of IL-11 expression compared with superficial, low-grade bladder cancer. It is demonstrated that the level of IL-11 was associated with tumor grade and stage in TCC. Thus, TCC that expresses a decreased level of IL-11 is more likely to have a poor histological grade and a poor predicted prognosis. Similarly, samples showing lower levels of IL-11 are more likely to fail to respond to treatment, develop recurrence and to have poor survival. These data indicated that IL-11 may be a predictor of prognosis in TCC.

Further study is required to formulate an arbitrary cut-off value for IL-11 in order for it to be of clinical significance to predict prognosis. Future research in this field may explain the downregulation mechanisms and reveal a new predictor in human bladder cancer prognosis.

In conclusion, IL-11 is downregulated in human bladder cancer cell lines, TCC and urine samples. Its level is associated with tumor grade and stage. We propose that reduced levels of IL-11 may be a mechanism of bladder cancer carcinogenesis and progression. It also may be a predictor of prognosis in TCC. Patients with reduced levels of IL-11 should receive more active treatment due to the more aggressive biology of TCC. Besides its prognostic value, IL-11 may represent a promising method for the development of adjuvant therapy for TCC.
