Abstract. Recent studies have focused on the role of endothelial cells during tumor radiotherapy, and the majority of studies have found that the rate of endothelial cell apoptosis determines the response of the tumor to ionizing radiation treatment. However, gene expression changes in human ovarian cancer-derived endothelial cells in response to X-ray radiation remains poorly understood. The present study was conducted to investigate the radiation-induced gene alterations in human ovarian cancer-derived endothelial cells and to provide novel potential targets for combined anti-angiogenesis and radiation therapy for the treatment of human ovarian cancer. Ovarian cancer-derived endothelial cells, which were harvested from six human ovarian epithelial carcinomas prior to and 4 h after 400 cGy X-ray irradiation, were analyzed using cDNA microarray technology. Significant genes were selected to corroborate the microarray experiments using a quantitative polymerase chain reaction (qPCR). A total of 28 genes common to all the cDNA microarray results were identified, of which 22 genes were found to be consistently upregulated or downregulated. Thirteen genes were upregulated persistently and nine genes downregulated persistently following irradiation with 400 cGy X-ray in comparison with the matched group. The majority of the significantly altered genes (≥2-fold change in expression) were found to have a role in vasculogenesis, cell cycle regulation, inflammation and the immune response, cell growth and apoptosis, nicotinamide metabolism, cell signaling, chemokines and cell adhesion. Eight randomly selected genes were corroborated using qPCR technology. Radiation-induced gene alterations in ovarian cancer-derived endothelial cells and gene-related pathways were associated with vasculogenesis and the radiosensitivity of human ovarian cancer, and may provide promising biomarkers for radiation and anti-angiogenesis treatments against ovarian carcinoma.

Introduction

Angiogenesis, which is essential for solid tumor growth, is a promising target for the treatment of ovarian cancer. The growth and proliferation of cancer cells is dependent on the nutrient supply from the self-supporting vasculature of the neoplasm (1). Angiogenesis has an important role in tumor invasion, migration and susceptibility to radiation (2-4). Additionally, angiogenesis and high expression levels of angiogenic factors are associated with an increased risk of metastasis and recurrence in ovarian cancer (5). The initial stage of angiogenesis depends on endothelial cells sprouting from pre-existing vessels and migrating (6). Endothelial cells self-regulate their growth, as well as regulating the growth of the surrounding tumor cells, through the autocrine and paracrine signaling pathways. In addition, endothelial cells secrete a variety of protease degradation factors that accelerate tumor invasion (7,8). Therefore, the targeting of endothelial cells is a key strategy in the development of anti-angiogenesis therapies for cancer (9).

To date, endothelial cells derived from human ovarian cancer have been extracted, the morphology and invasion characteristics of the cells have been demonstrated and the gene expression profiles of cancer-derived and normal ovarian endothelial cells have been reported (10). Whereas global genetic changes in ovarian cancer-derived endothelial cells have been characterized, there is little information regarding whole genome expression profiling in the ovarian cancer endothelium response to radiotherapy.

Radiotherapy has an important role in neoadjuvant, primary and adjuvant therapy for ovarian cancer. It has been shown that the efficacy of radiotherapy is affected by gene susceptibility (11). A series of genes that are closely associated with radiotherapy has been generated using gene microarray technology and has enhanced the understanding of the pathogenesis and progression of cancer (10,12). The aim of the present study was to screen genes that were closely associated with radiotherapy of ovarian cancer-derived endothelial cells using microarray technology, and to provide novel targets for radiation and anti-angiogenesis combination therapy for the treatment of human ovarian cancer.
Materials and methods

Patients and specimens. Fresh specimens of human epithelial ovarian cancer were obtained from six female patients aged 38-61 years, who had undergone surgery for ovarian cancer at the Shandong Cancer Hospital (Jinan, China). Informed consent was obtained from each patient and the use of fresh specimens was approved by the Medical Ethics Committee, Shandong Cancer Hospital. Fresh ovarian specimens were confirmed and diagnosed as ovarian epithelial cancer by a pathologist. Detailed clinicopathological features of each patient are listed in Table I.

Cancer-derived endothelial cell extraction, culture and irradiation. Endothelial cells were isolated from the six epithelial ovarian cancer specimens, in accordance with a previously described protocol (12). The sterile specimens were cut into 0.2-mm² pieces, digested with 0.5% human collagenase I for 30 min at 37°C and then filtered through a 70-µm metal mesh to remove the undigested specimens, followed by a 50-µm mesh to yield single cells. Several negative selections were performed, including erythrocyte hemolysis (NH₄Cl) and removal of monocytes, lymphocytes and granulocytes using anti-cluster of differentiation (CD)14, -CD45, and -CD64 DynaBeads (Dynal Biotech LLC, Brown Deer, WI, USA). Positive selections were then performed using anti-CD31 immunomagnetic beads using a magnetic separator (Dynal Biotech LLC).

The purified ovarian endothelial cells were incubated in endothelium culture medium which was supplemented with 20% fetal calf serum, 100 U/ml streptomycin, 100 U/ml penicillin, 0.2 U/ml insulin, 20 ng/ml basic fibroblast growth factor, 30 µg/ml endothelial cell growth supplement, 10 U/ml heparin and 5 µg/ml hydrocortisone in a 5% CO₂ incubator at 37°C. Ovarian endothelial cells in the logarithmic phase were divided into a radiation group and a matched group. At 37°C and incubated with rabbit anti-human von Willebrand factor (37°C and incubated with rabbit anti-human von Willebrand factor (Immuno Way, USA) for 1 h and 4',6-diamidino-2-phenylindole (DAPI); fluorescein isothiocyanate-labeled goat anti-rabbit immunoglobulin G (1:100) was added for 1 h and 4',6-diamidino-2-phenylindole (Sigma, St Louis, MO, USA) for 3-5 min.

Immunofluorescence staining. Ovarian endothelial cells were incubated for 24 h, washed with cold phosphate-buffered saline (PBS) and fixed with 4% paraformaldehyde solution for 25 min. The cells were subsequently washed again with cold PBS, prior to being permeabilized with 0.5% Triton X-100 for 15 min, blocked with 1% bovine serum albumin for 30 min at 37°C and incubated with rabbit anti-human von Willebrand factor (vWF) antibody (Immuno Way, Newark, DE, USA) for 10 h at 4°C in solution. Following washing, fluorescein isothiocyanate-labeled goat anti-rabbit immunoglobulin G (1:100) was added for 1 h and 4',6-diamidino-2-phenylindole (Sigma, St Louis, MO, USA) for 3-5 min.

RNA isolation and oligonucleotide array sequence analysis. Total RNA, which was extracted from unirradiated and irradiated ovarian endothelial cells, was reverse transcribed to cDNA and labeled with Cy5- and Cy3-deoxycytidine triphosphate, respectively. The Cy5- and Cy3-labeled cDNAs were hybridized to the Human Genome U133 Plus 2.0 Affymetrix oligonucleotide microarray (Affymetrix, Inc., Santa Clara, CA, USA). Arrays were scanned using a LuxScan™ scanner (CapitalBio Corporation, Beijing, China) and the images obtained were analyzed using the LuxScan 3.0 software (CapitalBio) using a LOWESS normalization method. To enhance the accuracy of the data analysis, dye swap hybridizations were performed and the average ratio of Cy5/Cy3 was calculated to evaluate the gene expression levels. Signaling pathways that were associated with significant alterations were identified using the pathway analysis software MAS 2.0 (accessed at www.capitalbio.com).

Quantitative polymerase chain reaction (qPCR). To confirm the results from the microarray assay, qPCR was performed using a SYBR Green RT-PCR kit (Applied Biosystems, Foster City, CA, USA) in accordance with the manufacturer's instructions for the ABI Prism 7000 system (Applied Biosystems). Eight genes, chemokine (C-X-C motif) ligand 12 (CXCL12); matrix metallopeptidase 2 (MMP2); interleukin 7 receptor (IL7R); nicotinamide N-methyltransferase (NNMT); insulin-like growth factor 1 (IGF1); oncostatin M (OSM); cyclin D1 (CCND1) and thrombospondin 1 (THBS1), were used to validate the microarray data. All the primer sequences that were designed for these genes are shown in Table II. The total RNA extraction method was performed as mentioned above, and the purified RNA was then reverse transcribed to cDNA in accordance with the Fermentas RT kit instructions (Applied Biosystems). qPCR was performed under the following conditions: Holding at 95°C for 10 min, followed by 40 cycles, which included preliminary denaturing at 95°C for 10 sec, annealing at 55°C for 10 sec and extension at 72°C for 15 sec. All qPCR reactions were performed in triplicate. The reaction data from the qPCR were evaluated using melting-curve analysis and agar gel electrophoresis sugar, respectively. The cycle threshold (Ct) method was used to calculate the relative level of gene expression and the 2⁻ΔΔCt method was used to calculate the average Ct values. These Ct values were normalized against GAPDH, which was used as internal control (13).

Statistical analysis. Data were analyzed using SPSS 17.0 statistical software (SPSS, Inc., Chicago, IL, USA). Statistical differences between the two groups were analyzed using the Student's t-test and evaluated using P-values. P<0.05 was considered to indicate a statistically significant difference.

Results

Ovarian endothelial cell characteristics. Primary-cultured ovarian microvascular endothelial cells, which contained anti-CD31 magnetic beads, exhibited the contact inhibition phenomenon and presented a typical cobblestone morphology (Fig. 1). The classical endothelial marker, vWF, was expressed in cancer-derived (Fig. 2A) and normal (Fig. 2B) ovarian microvascular endothelial cells, as demonstrated using the immunofluorescence assay.
Significantly upregulated and downregulated genes in ovarian endothelial cells. The cDNA microarray assay analysis was used to identify significant gene alterations following 400 cGy X-ray irradiation in primary cultured human ovarian cancer-derived microvascular endothelial cells. A total of 28 genes were identified in all independent experiments, and 22 genes were found to be significantly and consistently up- or downregulated (≥2-fold). Of all the differentially expressed genes, 13 genes were upregulated whilst nine were downregulated following 400 cGy X-ray irradiation in comparison with the control group (Tables III and IV). The majority of genes identified that were significantly altered (≥2-fold) were involved in the regulation of cell cycle (CCND1), cell adhesion (sialic acid binding Ig-like lectin 1, MMP9, MMP2 and MMP1), regulation of cell growth [IGF1, platelet-derived growth factor C (PDGFC), FBJ murine osteosarcoma viral oncogene homolog and TIMP metallopeptidase inhibitor 1], the immune response (major histocompatibility complex, class I, E and IL7R), apoptosis (DNA damage-binding protein 2 and FILIP1L), chemokines [chemokine (C-C motif) ligand 2 (CCL2), CCL8, CXCL1, CXC receptor 4 (CXCR4) and CXCL12], the inflammatory response [interleukin 6 (IL6) and IL18], growth factors (PDGFC, platelet-derived endothelial cell growth factor, tumor necrosis factor (ligand) superfamily, member 13b and growth differentiation factor 15), nicotinamide metabolism (NNMT), cell signaling (IGF1) and angiogenesis [thrombospondin 1 (THBS1)].

Pathway analysis. The interworking network of these gene-associated pathways, integrating information
from the Kyoto Encyclopedia of Genes and Genomes (www.genome.jp/kegg), Gene Map Annotator and Pathway Profiler (www.genmapp.org) and BioCarta (www.biocarta.com), are listed in Table V. Gene ontology analysis showed that the chemokine and NOD-like receptor signaling pathways were the most important.

**Corroboration of microarray data using qPCR.** Eight genes, which had different fold changes in expression, were randomly selected to corroborate the reproducibility of the cDNA microarray analysis results using a two-step fluorescent qPCR method. Upregulated genes comprised CXCL12 (7.64-fold), MMP2 (8.12-fold), IL7R (9.81-fold), NNMT (5.56-fold), IGF1 (4.06-fold) and THBS1 (3.77-fold), and downregulated genes comprised OSM (4.18-fold) and CCND1 (4.73-fold). The two-step qPCR was arranged so that each independent experiment was performed at least three times; the analysis results are shown in Fig. 3. The results from the qPCR were consistent with those from the microarray analysis and supported the reproducibility of the gene microarray data.

**Discussion**

In the present study, gene alterations in human ovarian cancer-derived microvascular endothelial cells in response to 400 cGy X-ray irradiation were identified using cDNA...
microarray analysis and qPCR technology. Following treatment with 400 cGy X-ray irradiation, a total of 28 genes were found to be differentially expressed (≥2-fold) in primary cultured ovarian cancer-derived endothelial cells compared with the control group. A number of significant genes and gene clusters were revealed in the present study, and these genes and gene clusters were found to be associated with tumor angiogenesis, cell cycle regulation, inflammation and the immune response, cell growth and apoptosis, nicotinamide metabolism, cell signaling, chemokines and cell adhesion. Radiation-induced gene alterations and gene-related pathways in endothelial cells may provide the theoretical basis for the combination of radiation and anti-angiogenesis therapy for the treatment of human ovarian cancer.

Radiotherapy exerts a cytotoxic effect on malignant tumors; however, low-dose radiation may induce neovascularization (14). In the present study, the expression of genes in the chemokine family, which activate the neoplasm-related immunoreaction, regulate neoplasm vasculogenesis and participate in neoplasm growth and metastasis, were found to be significantly modified (15). These altered chemokine-associated genes included CXCL1, CXCL12, CXCR4, CCL2 and CCL8. Wolff et al (16) showed a consistent upregulation pattern of CXCL1, CXCL12 and CXCR4 in head and neck tumor cells following X-ray irradiation. Kryczek et al (17) used an athymic mouse model to demonstrate that inhibition of the CXCL12/CXCR4 axis may inhibit human spongioblastoma regrowth following radiotherapy. CXCL1, CXCR4 and other chemokines were observed to be in an upregulated state when human umbilical vein endothelial cells were exposed to low-dose ionizing radiation (18). The data from the present study suggest that chemokines may have the potential to be targets for radiation and anti-vasculogenesis therapies for the treatment of ovarian cancer.

MMPs are known to be associated with neoplasm vasculogenesis and invasion. In the present study, it was found that MMP-2 and MMP-9 were overexpressed in radiation-induced ovarian cancer-derived endothelial cells. MMP-2 and MMP-9 overexpression has been found to be closely associated with ovarian cancer invasion and metastasis (19). Peng et al (20) reported that decreased MMP-2 and MMP-9 expression was associated with reduced angiogenesis in radiation therapy for nasopharyngeal carcinoma (20). Pratheeshkumar and
Kuttan (21) demonstrated that vernolide-A was capable of inhibiting radiation-induced neoplasm vasculogenesis by downregulating the angiogenic growth factors MMP-2 and MMP-9. Radiation-induced neoplasm vasculogenesis has also been successfully suppressed by MMP-2 and MMP-9 inhibitors (22,23). Therefore, MMP inhibitors, in combination with radiotherapy, may be a novel therapeutic strategy for the treatment of ovarian carcinoma.
The cytokine IL-6, which is an important regulator of tumor progression, has a pro-proliferative effect on endothelial cells (24). Preclinical trials have shown that the overexpression of IL-6 is associated with multidrug resistance, via the Janus kinase/signal transducer and activator of transcription (Jak/STAT) signaling pathway, and poor prognosis in ovarian cancer cells (25,26). In the present study, it was found that IL-6 was present in a high-expression state in ovarian cancer-derived endothelial cells in response to 400 cGy X-ray irradiation. Recently, Oh et al (27) found that the IL-6 gene was upregulated in breast cancer-derived endothelial cells following X-ray irradiation and knockdown of the c-jun N-terminal kinase or Akt signal transduction pathways using small interfering RNA (siRNA) to effectively attenuate the expression of IL-6 in irradiated endothelial cells. Yu et al (28) demonstrated using cytokine array analysis that the secretion of IL-6 increased in radiation-induced senescent cells, and it was shown using siRNA technology that the upregulated IL-6 expression accelerated tumor cell invasion. Despite this, the potential mechanisms of IL-6 in irradiated ovarian cancer-derived endothelial cells require further investigation.

THBS1, an effective neoplasm vasculogenesis inhibitor, is the target gene of the thrombospondin 1 (TSP1) protein. It has been shown that TSP1 can suppress cancerous cell growth by preventing vascular endothelial cells from coping with multiple vasculogenesis-stimulating factors. Rofstad et al (29) demonstrated that TSP1 not only prevented the development of distant disseminated micro-metastases following radiotherapy, but also inhibited the regrowth of irradiated primary human melanoma. The results from their study also confirmed that TSP1 may improve the susceptibility of human melanoma to radiation by enhancing the frequency of the cancer-associated endothelial cell apoptosis. Furthermore, Maxhimer et al (30) demonstrated that blocking the TSP1/CD47 pathway may protect the surrounding healthy tissue from radiolesion and improve tumor radiosensitivity. TSP1 acts via CD47 to inhibit the nitric oxide/cyclic guanosine monophosphate pathway, which may promote endothelial cell proliferation and survival (30-32). In the present study, it was found that THBS1 showed high levels of expression in ovarian cancer-derived endothelial cells following 400 cGy X-ray irradiation, compared with levels in control cells (3.54-fold increase). This suggests that THBS1 was the main factor enhancing the curative effect of radiotherapy in ovarian cancer-derived endothelial cells.

The FILIP1L gene, originally known as ‘downregulated in ovarian cancer’ or DOC1, has been previously demonstrated to be downregulated in various human malignant tumors and, in the present study, low expression levels were observed. Kwon et al (33) confirmed that the overexpression of FILIP1L has an important role in inhibiting cell proliferation and inducing apoptosis in human umbilical vein endothelial cells transfected with FILIP1L cDNA. Lu and Hallstrom (34) demonstrated that treatment with topoisomerase II chemotherapeutic agents induced FILIP1L expression in an ataxia telangiectasia mutated/ataxia telangiectasia and Rad3-related protein-dependent manner, and that the increased FILIP1L expression enhanced the sensitivity of human osteosarcoma cells to topoisomerase II chemotherapeutic agents. To the best of our knowledge, the present study is the first to demonstrate changes in FILIP1L gene expression in human ovarian cancer-derived endothelial cells in response to X-ray radiotherapy. Whether the FILIP1L gene is an effective radiation and anti-vasculogenesis therapy target requires further investigation; however, its function in ovarian endothelial cells and its antitumor effect make it a promising candidate gene.

Another gene of note is NNMT, which exhibited a high-expression state in the present study (4.13-fold increase in expression compared with control cells) and is widely known to participate in nicotinate and nicotinamide metabolism (35). It has been shown that nicotinamide can enhance the radiation response of human spongioblastoma in a Nude mouse model, and nicotinamide has also been shown to increase sensitivity to radiation in patients with bladder cancer (36,37). This suggests that NNMT expression is associated with the radiation response. Kassem et al (38) demonstrated that NNMT exhibited low expression levels in a radiosensitive cell line. However, the specific mechanism linking radiosusceptibility and NNMT in ovarian cancer has yet to be elucidated.

In the present study, signaling pathways that were associated with significant alterations in gene expression in vascular endothelial cells in response to X-ray radiation were identified using the pathway analysis software MAS 2.0. The majority of the pathways identified were found to be involved in cell proliferation and differentiation, cell adhesion, extracellular matrix regulation and cell migration, including the NOD-like receptor signaling pathway, the chemokine signaling channel and the Jak/STAT signaling pathway. The data from the present study suggest that these pathways may participate in regulating the behavior of ovarian cancer-derived endothelial cells following radiotherapy. However, the roles of these pathways in ovarian cancer radiotherapy remain inconclusive and require further investigation.

In conclusion, genes altered by X-ray radiation in human ovarian cancer-derived endothelial cells were identified in the present study. These genes were involved in angiogenesis, cell cycle regulation, inflammation and the immune response, cell growth and apoptosis, nicotinamide metabolism, cell signaling, chemokines and cell adhesion. The findings from the present study may be useful, not only to provide the theoretical foundation to predict anti-angiogenesis- and radiosensitivity-associated genes, but also as a means to identify potential and effective targets to improve the radiosensitivity of ovarian cancer cells. In future studies, additional investigations are required to define the role of these identified genes in vitro and in vivo.
