Abstract. Tumor necrosis factor-α-inducible protein-1 (TNFAIP1) plays a role in DNA synthesis, DNA repair, cell apoptosis and human diseases including cancer, and may be involved in tumor progression and metastases. However, little is known concerning the function of TNFAIP1 in human osteosarcoma (OS). The aim of the present study was to investigate the function and underlying mechanisms of TNFAIP1 in human OS. The expression of TNFAIP1 was examined by immunohistochemical assay using a tissue microarray procedure. A loss-of-function experiment was performed to explore the effects of lentiviral-mediated TNFAIP1 siRNA (siTNFAIP1) on cell proliferation, invasive potential and apoptosis by MTT and Transwell assays and flow cytometric analysis in OS (MG-63 and U-2 OS) cells. The results showed that the expression of TNFAIP1 protein was significantly increased in OS tissues compared with that in adjacent non-cancerous tissues (ANCTs) (73.3 vs. 48.9%, P=0.018), and was correlated with the distant metastasis of the patients with OS (P=0.029). Knockdown of TNFAIP1 suppressed cell proliferation and invasion, and induced cell apoptosis in the OS cells together with the downregulation of p65 nuclear factor-κB (NF-κB), proliferating cell nuclear antigen (PCNA) and matrix metalloproteinase-2 (MMP-2) and upregulation of caspase-3. Collectively, our findings indicate that high expression of TNFAIP1 is associated with distant metastasis of OS, and knockdown of TNFAIP1 inhibits the growth and invasion, and induces apoptosis in OS cells through inhibition of the NF-κB pathway, suggesting that TNFAIP1 may act as a potential therapeutic target for the treatment of cancer.

Introduction

Osteosarcoma (OS) is a primary malignant bone tumor mostly occurring in adolescents and young adults with a second peak at middle age (1). OS patients are generally treated with high doses of neoadjuvant chemotherapy to prevent the outgrowth of micrometastases (2). However, 45% of OS patients develop distant metastases, leading to the death of OS patients (3). OS is also a genetic disease, and single or multiple mutations in genes related to growth and metastasis form the molecular genetic basis of malignant transformation and tumor progression (4). Thus, identification of molecular targets that can be exploited in the clinic to treat metastatic disease is desperately needed.

Tumor necrosis factor-α-inducible protein-1 (TNFAIP1) is a protein which can be induced by tumor necrosis factor α (TNFα) and interleukin-6 (IL-6), and may play roles in DNA synthesis, cell apoptosis and human diseases (5). TNFAIP1 has been identified to be highly expressed in Alzheimer's disease brains (6) and hepatitis B virus (7), and is associated with diabetic nephropathy (8). Moreover, overexpression of TNFAIP1 was found to correlate with histological grade and a poor prognosis in breast cancer (9), and its allelic partner TNFAIP2 was found to be aberrantly expressed in malignant cells of classical Hodgkin lymphoma and primary mediastinal large B-cell lymphoma (10), and contributes to the rapid progression of cervical cancer (11), indicating TNFAIP may serve as a useful new marker of cancer.

TNFAIP1 expression was found to be downregulated in lipopolysaccharide (LPS)-induced liver injury (12). Yet, few reports have demonstrated the expression and function of TNFAIP1 in OS tissues. More importantly, TNFRSF11A gene encoding receptor activator of nuclear factor-κB (NF-κB) has been confirmed to be responsible for the progression of OS (13), and activation of NF-κB participates in the anti-apoptotic effect in TNFα-treated Ewing sarcoma cells (14). In the present study, the expression of TNFAIP1 was examined,
and its function and molecular mechanisms were evaluated in human OS. We found that knockdown of TNFAIP1 inhibited the growth and invasion, and induced apoptosis in OS cells through inhibition of the NF-κB pathway.

Materials and methods

Materials. The OS cell lines (MG-63 and U-2 OS) used for experiments were obtained from the Institute of Biochemistry and Cell Biology (Shanghai, China). Lentiviral-mediated TNFAIP1 siRNA (siTNFAIP1), the negative control (NC) vector, and virion-packaging elements were purchased from GeneChem (Shanghai, China). Human OS tissues and the corresponding adjacent non-cancerous tissues (ANCTs) were collected from the Department of Orthopedic Surgery, Changzheng Hospital. The OS tissue microarray was constructed by Shanghai Outdo Biotech Co. Ltd. (Shanghai, China). All the antibodies were purchased from Cell Signaling Technology (Boston, MA, USA). The cell apoptosis kit was from KeyGen Biology (China). The cytokine ELISA kit was obtained from BD Biosciences (San Diego, CA, USA). The Odyssey Infrared Imaging System was purchased from LI-COR BIOSCIENCES (Lincoln, NE, USA). The cell apoptosis kit was from KeyGen Biology (China).

Drugs and reagents. Dulbecco's modified Eagle's medium (DMEM) and fetal bovine serum (FBS) were purchased from Thermo Fisher Scientific Inc. (Waltham, MA, USA); TRIzol reagent and Lipofectamine 2000 were obtained from Invitrogen (Carlsbad, CA, USA); M-MLV reverse transcriptase was purchased from Promega (Madison, WI, USA); SYBR-Green Master Mix was obtained from Takara (Otsu, Japan); and the ECL Plus kit was obtained from GE Healthcare (Piscataway, NJ, USA). The cell apoptosis kit was from KeyGen Biology (China).

Clinical samples and data. The tissue microarray was prepared for immunohistochemical (IHC) analysis. Human OS tissues and the corresponding ANCTs were obtained from biopsies in a total of 45 consecutive OS cases admitted to our hospital from January 2005 to December 2011. The baseline characteristics of the patients before neoadjuvant chemotherapy are summarized in Table I. The present study was approved by the Medical Ethics Committee of the Second Military Medical University, and written informed consent was obtained from the patients or their parents before sample collection. Two pathologists respectively reviewed all of the cases.

Tissue microarray. The Advanced tissue arrayer (ATA-100; Chemicon International, Tamecula, CA, USA) was used to create holes in a recipient paraffin block and to acquire cylindrical core tissue biopsies with a diameter of 1 mm from the specific areas of the ‘donor’ block. The tissue core biopsies were transferred to the recipient paraffin block at defined array positions. The tissue microarrays contained tissue samples categorized into two groups: low-level TNFAIP1 expression (score 0-3) and high-level TNFAIP1 expression (score 4-12). The scoring was independently assessed by two pathologists.

Immunohistochemical staining. Tissue microarray sections were processed for IHC analysis of TNFAIP1 protein as follows. IHC examinations were carried out on 3-mm thick sections. For anti-TNFAIP1 IHC, unmasking was performed with 10 mM sodium citrate buffer, pH 6.0, at 90˚C for 30 min. For anti-TNFAIP1 IHC, antigen unmasking was not necessary. Sections were incubated in 0.03% hydrogen peroxide for 10 min at room temperature to remove endogenous peroxidase activity, and then in blocking serum [0.04% bovine serum albumin (A2153; Sigma-Aldrich, Shanghai, China) and 0.5% normal goat serum (X0907; Dako Corporation, Carpinteria, CA, USA) in phosphate-buffered saline (PBS)] for 30 min at room temperature. The anti-TNFAIP1 antibody was used at a dilution of 1:200. The antibody was incubated overnight at 4˚C. Sections were then washed three times for 5 min in PBS. Non-specific staining was blocked with 0.5% casein and 5% normal serum for 30 min at room temperature. Finally, staining was developed using diaminobenzidine substrate, and sections were counterstained with hematoxylin. Normal serum or PBS was used to replace the anti-TNFAIP1 antibody in the negative controls.

Quantification of protein expression. The expression of TNFAIP1 was semi-quantitatively estimated as total immunostaining scores, which were calculated as the product of a proportion score and an intensity score. The proportion and intensity of the staining were evaluated independently by two observers. The proportion score reflected the fraction of positive staining cells (0, none; 1, <10%; 2, 10 to <25%; 3, >25 to 50%; 4, >50%), and the intensity score represented the staining intensity (0, no staining; 1, weak; 2, intermediate; 3, strong). Finally, a total expression score was given ranging from 0 to 12. Based on the analysis in advance, TNFAIP1 expression was categorized into two groups: low-level TNFAIP1 expression (score 0-3) and high-level TNFAIP1 expression (score 4-12).

Cell culture and transfection. OS cell lines were cultured in DMEM supplemented with 10% heat-inactivated FBS, 100 U/ml of penicillin and 100 µg/ml of streptomycin. Cells in this medium were placed in a humidified atmosphere containing 5% CO2 at 37˚C. Cells were subcultured at a 1:5 dilution in medium containing 300 µg/ml G418 (an aminoglycoside antibiotic, commonly used as a stable transfection reagent in molecular genetic testing). On the day of transduction, OS cells were replated at 5x10⁶ cells/well in 24-well plates containing serum-free growth medium with Polybrene (5 mg/ml). When reaching 50% confluency, the cells were transfected with the recombinant experimental or control virus at the optimal multiplicity of infection (MOI) of 50, and cultured at 37˚C in 5% CO2 for 4 h. Then the supernatant was discarded and serum containing growth medium was added. At 4 days post-transduction, transduction efficiency was measured by the frequency of green fluorescent protein (GFP)-positive cells.

Quantitative real-time PCR. To quantitatively determine the mRNA expression level of TNFAIP1 in OS cells, real-time
PCR was performed. Total RNA was extracted from each clone using TRIzol according to the manufacturer's protocol. Reverse transcription was carried out using M-MLV, and cDNA amplification was performed using the SYBR-Green Master Mix kit according to the manufacturer's guidelines. The TNFAIP1 gene was amplified using a specific oligonucleotide primer, and the β-actin gene was used as an endogenous control. Data were analyzed using the comparative Ct method (2−ΔΔCt). Three separate experiments were performed for each clone.

Western blot assay. OS cell lines were harvested and extracted using lysis buffer (Tris−HCl, SDS, mercaptoethanol and glycerol). Cell extracts were boiled for 5 min in loading buffer, and then an equal amount of cell extracts was separated on 15% SDS-PAGE gels. Separated protein bands were transferred onto polyvinylidene fluoride (PVDF) membranes, which were subsequently blocked in 5% skim milk powder. Primary antibodies against TNFAIP1, p65NF-κB, PCNA, matrix metalloproteinase-2 (MMP-2) and caspase-3 were diluted according to the manufacture's instructions and incubated overnight at 4°C. Subsequently, horseradish peroxidase-linked secondary antibodies were added at a dilution of 1:1,000 and incubated at room temperature for 2 h. The membranes were washed 3 times with PBS, and the immunoreactive bands were visualized using the ECL Plus kit according to the manufacturer's instructions. The relative protein levels in the different cell lines were normalized to the concentration of β-actin. Three separate experiments were performed for each clone.

Cell proliferation assay. Cell proliferation was analyzed using the MTT assay. Briefly, cells infected with the siTNFAIP1 virus were incubated in 96-well-plates at a density of 1x10⁴ cells/well with DMEM supplemented with 10% FBS. Cells were treated with 20 µl of MTT dye at 0, 24, 48 and 72 h, and subsequently incubated with 150 µl of DMSO for 5 min. The color reaction was measured at 570 nm using an Enzyme Immunoassay Analyzer (Bio-Rad, Hercules, CA, USA). The proliferation activity was calculated for each clone.

Transwell invasion assay. Transwell filters were coated with Matrigel (3.9 µg/µl; 60-80 µl) on the upper surface of a polycarbonate membrane (diameter, 6.5 mm; pore size, 8-µm). After incubation at 37°C for 30 min, the Matrigel solidified and served as the extracellular matrix for analysis of tumor cell invasion. Harvested cells (1x10⁵) in 100 µl of serum-free DMEM were added into the upper compartment of the chamber. A total of 200 µl of conditioned medium derived from NIH3T3 cells was used as a source of chemoattractant, which was placed in the bottom compartment of the chamber. After 24 h of incubation at 37°C with 5% CO₂, the medium was removed from the upper chamber. The non-invaded cells on the upper side of the chamber were scraped off with a cotton swab. Cells that had migrated from the Matrigel into the pores of the inserted filter were fixed with 100% methanol, stained with hematoxylin, then mounted and dried at 80°C for 30 min. The number of cells invading through the Matrigel was counted in 3 randomly selected visual fields from the central and peripheral portion of the filter by using an inverted microscope (x200 magnification). Each assay was repeated 3 times.

Figure 1. Expression of TNFAIP1 protein in OS tissues (magnification, x400). OS tissues were immunohistochemically stained with an anti-TNFAIP antibody. The positive expression of TNFAIP1, mainly localized in the nucleus, was increased in the OS tissues compared with the ANCTs. (A) Positive expression in OS tissues. (B) Negative expression in OS tissues. (C) Positive expression in ANCTs. (D) Negative expression in ANCTs. TNFAIP1, tumor necrosis factor-α-inducible protein-1; OS, osteosarcoma; ANCTs, adjacent non-cancerous tissues.

Analysis of cell apoptosis. To detect cell apoptosis, OS cells treated with siTNFAIP1 were trypsinized, washed with cold PBS and resuspended in binding buffer according to the instructions provided in the apoptosis kit. FITC-Annexin V and PI were added to the fixed cells for 20 min in darkness at room temperature. Then, Annexin V binding buffer was added to the mixture before the fluorescence was measured on the FACSort flow cytometer. Cell apoptosis was analyzed using CellQuest software (Becton-Dickinson, USA). Three separate experiments were performed for each clone.

Statistical analysis. SPSS 20.0 was used for statistical analysis. Kruskal-Wallis H and Chi-square tests were used to analyze the expression rate in all groups. One-way analysis of variance (ANOVA) was used to analyze the differences between groups. The LSD method of multiple comparisons was used when the probability for ANOVA was statistically significant. Statistical significance was set at P<0.05.

Results

Expression of TNFAIP1 in OS tissues. The expression of TNFAIP1 protein was evaluated using IHC staining in OS tissues. Different levels of positive expression of TNFAIP1 protein were detected in the OS tissues (Fig. 1A and B) and the ANCTs (Fig. 1C and D). Positive TNFAIP1 immunostaining was mainly localized in the nucleus of the OS tissue cells. According to the TNFAIP1 immunoreactive intensity, the positive expression of TNFAIP1 in the OS tissues was significantly increased compared with that in the ANCTs (P=0.018) (Table II).

Correlation of TNFAIP1 expression with clinicopathological characteristics. The correlation of TNFAIP1 expression with various clinicopathologic factors was analyzed. As
shown in Table I, increased expression of TNFAIP1 was closely correlated with the distant metastasis of OS patients (P=0.029). However, no significant association was found between TNFAIP1 expression and other factors including age, gender of the patients, and histology and Ennecking stage of the tumor (P>0.05, respectively).

**Effect of TNFAIP1 knockdown on the expression of NF-κB.**
Lentiviruses of different multiplicity of infection (MOI) were transfected into OS cells (MG-63 and U-2 OS), and the transfection efficiency of siTNFAIP1 (MOI=50) reached >70%. After siTNFAIP1 was transfected into the OS cells for 24 h, the expression levels of TNFAIP1 mRNA (Fig. 2A and B) and protein levels of TNFAIP1 and p65NF-κB (Fig. 2C and D) were detected by real-time PCR and western blotting, indicating decreased expression of TNFAIP1 and p65NF-κB in the siTNFAIP1 group compared with the levels in the NC and CON groups (each *P*<0.01). TNFAIP1, tumor necrosis factor-α-inducible protein-1; NF-κB, nuclear factor-κB; OS, osteosarcoma; siTNFAIP1, TNFAIP1 siRNA; NC, negative control.

**Effect of TNFAIP1 knockdown on cell proliferation.**
Deregulated cell proliferation is a hallmark of cancer. To confirm the effect of TNFAIP1 on OS cell growth, we examined cell proliferative activities by MTT assay. The results showed that knockdown of TNFAIP1 diminished the proliferative activities of the OS cells in a time-dependent manner compared to the NC group (Fig. 3A and B). In addition, the expression level of PCNA protein, examined by western blotting (Fig. 3C and D), was found to be significantly downregulated in the siTNFAIP1 group when compared with the level in the NC and CON groups.

Table II. Expression of TNFAIP1 protein in OS tissues.

TNFAIP1, tumor necrosis factor-α-inducible protein-1; OS, osteosarcoma; ANCTs, adjacent non-cancer tissues.
Effect of TNFAIP1 knockdown on cell invasion. To determine the effect of TNFAIP1 on cell invasion, a Transwell assay was performed. The invasive potential of tumor cells in the Transwell assay was determined by the ability of cells to invade a matrix barrier containing laminin and type IV collagen, the major components of the basement membrane. Representative micrographs of Transwell filters are shown in Fig. 4A and B. We found that the invasive potential of OS cells was markedly lowered in the siTNFAIP1 group when compared to the invasive potential in the NC and CON groups (P<0.01) (Fig. 4C and D). In addition, the expression level of MMP-2 protein, examined by western blotting (Fig. 4E and F), was found to be significantly downregulated in the siTNFAIP1 group when compared to the level in the NC and CON groups.
Effect of TNFAIP1 knockdown on cell apoptosis. To determine whether TNFAIP1 affects OS cell apoptosis, flow cytometric analysis with PI/FITC-Annexin V staining was performed. We found that the apoptosis indices of the OS cells were significantly higher in the siTNFAIP1 group when compared to the indices in the NC and CON groups (Fig. 5A-D). Additionally, to determine whether TNFAIP1 regulates the expression of caspase-3 protein, western blotting was carried out. The protein level of caspase-3 was found to be upregulated in the siTNFAIP1 group in comparison with the level in the NC and CON groups (Fig. 5E and F).

Discussion

TNF-α is an inflammatory cytokine that is present in the microenvironment of many types of tumors, and is known to promote tumor progression. Overexpression of TNFAIP1 or TNFAIP2 correlates with tumor invasion and metastasis, and serves as an independent prognostic indicator for breast cancer (9) and nasopharyngeal carcinoma (15). The TNFAIP2 miRNA binding site (s8126 T>C SNP) is also correlated with a significantly elevated risk of gastric cancer, suggesting a marker for susceptibility to gastric cancer (16). To verify the correlation of TNFAIP1 expression with OS, we examined the expression of caspase-3 protein, western blotting was carried out. The protein level of caspase-3 was found to be upregulated in the siTNFAIP1 group in comparison with the level in the NC and CON groups (Fig. 5E and F).

Application of NF-κB promotes the development of OS (14), while inhibition of NF-κB activity suppresses the tumorigenicity of Ewing sarcoma EW7 cells (24). It has been reported that NF-κB-mediated transcriptional upregulation of TNFAIP2 by the Epstein-Barr virus oncoprotein, LMP1, promotes cell motility in NPC (20). However, few studies have shown that TNFAIP1 inhibits the transcriptional activities of NF-κB (25). In the present study, we found that knockdown of TNFAIP1 downregulated the expression of NF-κB at the translational level in OS cells, suggesting that TNFAIP1 may promote the progression of OS through activation of the NF-κB pathway.
the expression of PCNA (28), MMP-2 (29) and apoptosis (30). Moreover, it was found that TNFAIP1 promotes cell growth and gene amplification in a PCNA-dependent way (5,31), yet no report has demonstrated the regulation of the expression of MMP-2 and caspase-3 by TNFAIP1. In the present study, we found that knockdown of TNFAIP1 downregulated the expression of PCNA and MMP-9 and upregulated the expression of caspase-3 in OS cells, suggesting that TNFAIP1 may promote the progression of OS through NF-κB pathway-mediated regulation of PCNA, MMP-2 and caspase-3 expression.

In conclusion, our findings indicate that high expression of TNFAIP1 is associated with the distant metastasis of OS, and knockdown of TNFAIP1 inhibits the growth and invasion, and induces apoptosis in OS cells through inhibition of the NF-κB pathway, suggesting that TNFAIP1 may act as a potential therapeutic target for the treatment of cancer.
