Abstract. Inhibition of angiogenesis is an important therapeutic strategy for advanced stage prostate cancer (PCa). RhoA/Rho-associated protein kinases (ROCK) are key regulators of the cytoskeleton and have been implicated in PCa angiogenesis. We investigated the anti-angiogenic effects of fasudil, a ROCK inhibitor, on PCa-induced angiogenesis \textit{in vitro}. Proliferation of PCa-conditioned human umbilical vein endothelial cells (HUVECs) was assessed using a bromodeoxyuridine (BrdU) assay, and migration was assessed with a wound healing assay. \textit{In vitro} angiogenesis of PCa-conditioned HUVECs was evaluated by tube formation and a spheroid sprouting assay. Fasudil inhibited PCa-induced endothelial cell proliferation at a concentration of 100 µM, and also decreased PCa-induced endothelial cell migration at a concentration of 30 µM. In the \textit{in vitro} angiogenesis assay, fasudil exerted a more significant effect. Tube formation was significantly inhibited at fasudil concentrations exceeding 3 µM, and spheroid sprouts were significantly thinner and shorter (at fasudil concentrations of 10 and 30 µM, respectively). Western blotting results showed that expression of phosphorylated myosin phosphatase target subunit 1 (MYPT-1) was significantly lower after fasudil treatment, confirming that fasudil inhibited ROCK activity in these model systems. These data suggest that fasudil may be a useful anti-angiogenic agent for PCa.

Introduction

Prostate cancer (PCa) is the most common malignancy and the second leading cause of cancer-related death in men in Western countries. Advanced and metastatic stages of the disease are found in 35% of patients with PCa diagnosed at autopsy (1). Among patients with localized cancer who are eligible for radical prostatectomy, ~35% will develop recurrence (metastatic disease) within 10 years of surgery (2,3).

Androgen deprivation therapy (ADT) can be effective in patients who present with or progress to advanced or metastatic disease. Unfortunately, the median duration of response to ADT is limited to between 8 months and 3 years (4), and these patients will eventually become castration resistant. Chemotherapy is an effective treatment for castration-resistant PCa, but the median duration of response is only 10.3 months (5). There is clearly an urgent need to develop additional systemic interventions for patients with progressive PCa. Angiogenesis plays a crucial role in PCa progression and metastasis. Microvessel density (MVD) has been found to be more prominent in PCa than in benign prostatic hyperplasia (BPH) and normal tissue (6,7). It has been reported that MVD increases with increased Gleason's score, particularly in poorly differentiated PCa (8). MVD was also significantly correlated with cancer-specific survival in 221 patients with PCa followed up for a median of 15 years (9).

Vascular endothelial growth factor (VEGF) is the most prominent regulator of physiological angiogenesis and has been correlated with increased levels of angiogenesis in clinical studies comparing PCa with BPH (7). Higher VEGF expression and serum levels have also been found in patients with metastasis or poorly differentiated tumors, as well as in those with a poor prognosis (10-13). However, it has become increasingly apparent that current anti-angiogenic therapy targeting VEGF has only a modest effect in the clinical setting.

RhoA and its downstream effector, Rho-associated protein kinase (ROCK), serve as key regulators of extracellular stimulus-mediated signaling networks that are involved in various cellular processes, including motility, mitosis, proliferation and apoptosis (14). Suppression of the RhoA/ROCK signaling pathway with the ROCK inhibitor, Y-27632, was found to inhibit VEGF-induced angiogenesis \textit{in vitro} (15). Another ROCK inhibitor, fasudil, has been shown to inhibit VEGF-induced angiogenesis \textit{in vitro} and \textit{in vivo} (16). A study carried out on endothelial cells from transgenic adenocarcinoma of the mouse prostate (TRAMP) mice revealed that their behavior correlated with a constitutively high level of baseline activity of Rho GTPase and ROCK (17). This suggests that the

RhoA/ROCK pathway has an important role in PCA angiogenesis. However, the anti-angiogenic effects of ROCK inhibitors in PCAs are unclear. We investigated the role of fasudil, a ROCK inhibitor, that has been approved for clinical use for pulmonary arterial hypertension, on PCA-induced angiogenesis in vitro.

Materials and methods

Cell culture. Human umbilical vein endothelial cells (HUVECs) were purchased from PromoCell (C-12200; Heidelberg, Germany) and cultured in endothelial cell growth medium (C-22010; PromoCell). Cultures were maintained at 37°C in a humidified atmosphere containing 5% CO₂. Subcultures were obtained by trypsination and were used for experiments at passages 3 to 9. Before performing the experiments, the cells were made quiescent by incubating overnight in endothelial cell basal medium (C-22210) containing 0.5% (w/v) fetal bovine serum (FBS). The PCa cell line, PC-3, was purchased from The European Collection of Cell Cultures (Little Chalfont, UK), according to the manufacturers’ instructions. In brief, HUVECs were plated in 96-well microculture plates (3x10³ cells/well). In each group, the medium was replaced with basal medium without FBS, and the supernatants were harvested after a 24-h incubation to serve as conditioned medium (PC3CM). Recombinant human VEGF 165 was purchased from R&D Systems (293-plates (3x10³ cells/well)) according to the manufacturers’ instructions. In brief, HUVECs were plated in 96-well microculture plates (3x10³ cells/well). In each group, the medium was replaced with basal medium without FBS, and the supernatants were harvested after a 24-h incubation to serve as conditioned medium (PC3CM). Recombinant human VEGF 165 was purchased from R&D Systems (293-plates (3x10³ cells/well)).

Proliferation Biotrak ELISA System; RPN250; GE Healthcare, Little Chalfont, UK), according to the manufacturers’ instructions. In brief, HUVECs were plated in 96-well microculture plates (3x10³ cells/well). After a 48-h incubation at 37°C in a 5% CO₂ atmosphere, with or without fasudil (1-100 µM), 10 µl BrdU labeling reagent was added, and the cells were cultured for a further 2 h. Cells were washed twice with Dulbecco’s PBS (D8537; Sigma-Aldrich, St. Louis, MO, USA), fixed with fixative solution and then blocked with blocking buffer. BrdU incorporation was revealed by incubation with 100 µl/well horseradish peroxidase (HRP)-labeled anti-BrdU working solution for ~90 min. Tetramethylbenzidine (TMB) substrate at room temperature was added at 100 µl/well for 20 min. Absorbance was measured at 450 nm using a microplate reader. All determinations were performed in octuplicate, and each experiment was repeated three times.

Western blot assay. Protein was extracted on ice from the cultured HUVECs with cold RIPA lysis buffer (9806; Cell Signaling Technology, Boston, MA, USA) containing Pierce™ Protease and Phosphatase Inhibitor (88669; Thermo Scientific). Equal amounts of protein were subjected to sodium dodecyl sulfate polyacrylamide gel electrophoresis and then electrotransferred onto nitrocellulose membranes. The membranes were blocked for 1 h with 5% (w/v) non-fat milk in PBS-0.1% (v/v) Tween-20 (PBST) and incubated with primary antibodies against MYPT-1 (1:1,000; sc-25618; Santa Cruz Biotechnology), anti-ROCK1 (1:500; ABS45; Millipore, Billerica, MA, USA), anti-ROCK2 (1:1,000; sc-1851; both from Santa Cruz Biotechnology) and β-actin (1:500; ab8229; Abcam, Cambridge, UK) overnight at 4°C. Finally, the membrane was incubated with HRP-conjugated secondary antibodies as follows: goat anti-mouse IgG-HRP (1:5,000; sc-25618; Santa Cruz Biotechnology), rabbit anti-goat IgG-HRP (1:10,000; sc-2768; Santa Cruz Biotechnology), goat anti-rabbit IgG-HRP (1:10,000; sc-2004; Santa Cruz Biotechnology) for 1 h at room temperature. After washing three times with PBST, proteins were detected using the ChemiDoc™ XRS system. Quantification of the digital images was performed by measuring the ratio of the migration area to the total area of the wound gap. Each experiment was repeated three times.

Spheroid sprouting assay. HUVECs were suspended in culture medium containing 0.2% (w/v) methylcellulose (Sigma-Aldrich) and seeded in non-adherent round-bottom 96-well plates (Greiner, Frickenhausen, Germany). All suspended cells formed a single spheroid in each well of defined size and cell number (~400 cells/spheroid). Spheroids were fixed and embedded in 1.5 mg/ml collagen gel. The gel containing spheroids was transferred to pre-warmed 24-well plates and allowed to polymerize for 30 min. Endothelial basal medium or PC3CM with or without fasudil (1-100 µM) was then added to the surface of the gel (500 µl/well). After 16 h, images were captured using a Leica inverted microscope. Sprouting was quantified using NIH ImageJ software by measuring the cumulative sprout length, which consisted of every sprout from 10 spheroids in each group.

Cell migration assay. Cell motility was assessed using a wound-healing migration assay. HUVECs were seeded to full confluency in 6-well plates. The following day, a uniform wound was made using a 2-µl pipette tip, and the cells were washed twice with PBS. After incubation for 24 h with or without fasudil (1-100 µM) in the control, PC3CM and VEGF groups, the cells were fixed and photographed. Photographic imaging was performed using a Leica inverted microscope. Cell migration was quantified by measuring the ratio of the migration area to the total area of the wound gap. Each experiment was repeated three times.

Tube formation assay. Ninety-six-well plates were chilled to 4°C and coated with 50 µl of Matrigel (354234; BD Biosciences, Oxford, UK) per well. Freshly passaged HUVECs were seeded onto the gel. Endothelial tube morphogenesis was carried out in the presence or absence of fasudil (3-30 µM). Endothelial tube formation was observed after 16 h and photographed under phase contrast microscopy using a Leica inverted microscope. Quantification of the digital images was performed by counting the total number of tubes in five 40x fields, and total tube length was quantified using ImageJ™ software (NIH, Bethesda, MD, USA). Tube formation was expressed as fold change or percentage, compared to the controls. All determinations were repeated three times, and each experiment was repeated three times.
were visualized using an ECL Prime Western blotting detection kit (GE Healthcare). Photographs of the protein bands were captured using a digital imaging system (ImageQuant LAS; GE Healthcare), and densitometric measurements of band intensity in the western blotting were performed using NIH ImageJ software. The results shown are representative of three or more independent experiments.

Results

Fasudil inhibits PC3CM-induced HUVEC proliferation. Endothelial cell proliferation is crucial for angiogenesis. PC3CM-treated HUVECs were exposed to fasudil concentrations ranging from 1 to 100 µM, and HUVEC proliferation was examined using a BrdU assay. Fasudil concentrations of ≥30 µM had a significant inhibitory effect on PC3CM-induced cell proliferation, while proliferation in the control group was unchanged (Fig. 1).

Fasudil inhibits PC3CM-induced HUVEC migration. The inhibitory effects of fasudil on endothelial cell motility were assessed using a wound-healing migration assay. Fasudil (30 µM) significantly decreased the number of cells migrating into the scratched gap in the control, PC3CM and VEGF groups, indicating the potent inhibitory effect of fasudil on HUVEC movement and migration. VEGF increased HUVEC migration significantly more than PC3CM-induced HUVEC migration. After treatment with 30 µM fasudil, all migrations decreased to similar levels (Fig. 2).

Fasudil inhibits PC3CM-induced HUVEC tube formation. The effect of fasudil on capillary-like structure formation in vitro was examined using a 3-dimensional (3D) Matrigel
assay. When seeded onto Matrigel, HUVECs form tube structures and connect with each other, mimicking the in vivo process of angiogenesis. Sixteen hours after seeding, untreated HUVECs exhibited a clear capillary-like network formation. However, fasudil treatment dramatically decreased the capillary-like network formation in a dose-dependent manner. As fasudil concentration increased, total tube length gradually decreased (Fig. 3).
Fasudil inhibits PC3CM-induced ROCK activity. HUVECs were cultured in either basal medium (Ctrl), PC3CM, or basal medium containing VEGF (30 ng/ml) and treated with 30 µM fasudil or left untreated. ROCK activity was detected by immunoblotting with anti-ROCK1 and anti-ROCK2 antibodies. ROCK activity was detected by phosphorylation of the downstream effector, MYPT-1, with anti-phospho-MYPT-1 and anti-MYPT-1 antibodies. (A) Representative images of western blots are shown. The relative density of each blot was quantified as fold-expression relative to the control. The data shown are the mean ± SEM of 6 independent experiments. PC3CM increased pMYPT-1 expression and fasudil decreased pMYPT-1 expression (B) without any significant changes in MYPT-1 (C), resulting in an increase in the pMYPT-1/MYPT-1 ratio (D) in the PC3CM group and a decrease in this ratio after fasudil treatment. (E and F) PC3CM increased ROCK1 and ROCK2 expression while fasudil had no effect on ROCK expression. HUVECs, human umbilical vein endothelial cell; MYPT, myosin phosphatase target subunit 1; PCa, prostate cancer; PC3CM, PCa cell line PC3-conditioned media; ROCK, Rho-associated protein kinase; SEM, standard error of the mean; VEGF, vascular endothelial growth factor.

*Fasudil inhibits PC3CM-induced HUVEC spheroid sprouting.* In the sprout formation assay, HUVECs seeded in non-adhesive conditions in round bottom 96-well plates contributed to the formation of a single spheroid with a quiescent, non-proliferating surface monolayer within 24 h. The spheroids were then embedded in a 3D collagen matrix.
In the untreated control group, baseline sprouting was low (Fig. 4Aa). When cultured with PC3CM (Fig. 4Ab), baseline sprouting increased dramatically, although it was still less than that in the cells cultured with basal medium containing 30 ng/ml VEGF (Fig. 4Ac). Sprouting was almost completely inhibited by treatment with 100 µM fasudil (Fig. 4Ad-f). We then examined the dose-dependent response of fasudil on PCa-induced HUVEC sprouting. As shown in Fig. 4B, fasudil decreased HUVEC sprouting in a dose-dependent manner and 100 µM fasudil again inhibited sprouting almost completely.

Furthermore, when treated with increasing concentrations of fasudil, the sprouts became thinner and the HUVEC nucleus seldom emerged from the spheroids. These sprouts resembled cell protrusions, were markedly thinner compared with the untreated HUVEC sprouts, and were more abundant compared with the ordered architecture of the single HUVEC spheroid sprouts (Fig. 4B).

**Discussion**

To our knowledge, there have been no previous reports on the effects of fasudil on PCa-induced angiogenesis. In this study, HUVECs were cultured with the PCa cell line PC3CM to mimic endothelial cells in PCa tissue. Fasudil was then added to examine its effects on PC3CM-induced HUVECs using *in vitro* angiogenesis assays.

When cultured with PC3CM, ROCK1 and ROCK2 expression increased in the HUVECs, as did pMYPT-1 and total MYPT-1 expression. The pMYPT-1/MYPT-1 ratio was also increased. This indicates activation of the RhoA/ROCK pathway in PC3CM-stimulated HUVECs. It has been reported that endothelial cells in PCa tissue from TRAMP mice, a spontaneous PCA mouse model, have a constitutively high baseline level of activity of Rho GTPase and its downstream effector ROCK (17). This suggests that the RhoA/ROCK pathway plays a crucial role in PCa angiogenesis. HUVECs cultured in PC3CM share some of the characteristics of PCa endothelium and can therefore be used to represent it.

Angiogenesis involves a complex series of events that take place in a multi-step process. Endothelial cells migrate through the basement membrane toward an angiogenic stimulus. The leading front of migrating cells is driven by enhanced proliferation of endothelial cells, followed by the formation of capillary tubes via endothelial cell organization. The RhoA/ROCK pathway plays a role in each of these steps.

We evaluated the effects of fasudil on each of these steps in PCa-induced HUVECs. Fasudil was found to inhibit PC3CM-induced HUVEC proliferation, migration, tube formation and spheroid sprouting. This is in accordance with previous studies on VEGF-induced endothelial cell proliferation, migration and tube formation after treatment with the RhoA inhibitor, C3, or ROCK inhibitors, Y-27632 and fasudil (15,16,18).

It is interesting to note the morphological changes that occurred in the spheroid sprouting assay after treatment with fasudil. After treatment with 10 µM fasudil, the sprouts were much thinner than those on untreated cells. However, the HUVEC nucleus was observed less frequently moving out of the spheroids than in the controls. The movement of the nucleus decreased as the fasudil concentration increased, whereas sprouting was not affected until the concentration of fasudil exceeded 30 µM. These sprouts were more akin to cell protrusions, were markedly thinner compared with PC3CM-induced HUVEC sprouts, and were more abundant and disorganized compared with the ordered architecture of single HUVEC spheroid sprouting.

In conclusion, fasudil significantly inhibits the key steps of endothelial cell angiogenesis, including proliferation, migration and capillary tube formation, in a dose-dependent manner. These effects may be due to inhibition of ROCK activity induced by PCa cell secretions. Fasudil may be a useful anti-angiogenic agent and should be investigated further for its potential role in the anti-angiogenic treatment of PCa.
