Abstract. Accumulating evidence indicates that resistin-like molecule-α (RELM-α) is involved in angiogenesis, while the clinical significance and the exact role of RELM-α in gastric cancer remain obscure. The aim of the present study was to evaluate the clinical significance of RELM-α in gastric cancer, and to investigate its effective mechanisms in order to identify a potential therapeutic target. The expression levels of RELM-α in 92 gastric cancer and adjacent normal tissues were investigated and the relationship between RELM-α expression and the clinicopathological characteristics was explored. To investigate the potential role of RELM-α in gastric cancer cell biological behavior, the cell proliferation, migration and invasion assays were conducted using two gastric cancer cell lines (SGC7901 and MKN45). We also assessed whether RELM-α gene silencing modulates angiogenesis using small interference RNA in cancer cell lines, and investigated its effect on nuclear factor (NF)-κB activation and vascular endothelial growth factor (VEGF) and MMP-9 expression. Contrasting sharply with the strong RELM-α-positive tumors, adjacent normal tissues and cell lines exhibited negative or weakly positive expression (P<0.01). High expression level of RELM-α was associated with advanced stage and tumor size (P<0.01). The silencing of RELM-α expression by Ad5/F35-siRNA treatment significantly inhibited cell migratory and invasive ability in SGC7901 and MKN45 gastric cancer cells compared with the control and Ad5/F35 vector-transfected cell lines (P<0.01). However, the silencing of RELM-α expression also significantly blocked NF-κB activation and attenuated VEGF and MMP-9 expression. The data demonstrated that RELM-α is a promising novel biomarker of angiogenesis in patients with gastric cancer. The study identified that the silencing of RELM-α expression may regulate the proliferation, invasion and migration of gastric cancer cells by targeting VEGF/MMP-9, and the mechanism involved tissue angiogenesis via the NF-κB signaling pathway.

Introduction

Gastric cancer is a disease with one of the poorest prognoses, and is the second leading cause of tumor-related mortality worldwide. The 5-year overall survival is 25% or less, particularly in the USA, Europe and China (1,2). Every year, 1 million new cases of gastric cancer are diagnosed and 700,000 individuals succumb to this disease worldwide (3). Most patients with gastric cancer are diagnosed with advanced gastric cancer, and the overall survival rate remains poor. There is a need for new prognostic tumor markers that provide more effective therapeutic targets for gastric cancer.

Resistin-like molecule (RELM)-α belongs to the RELM family which are potent innate immune-modulating molecules which are implicated in Th2-associated mucosal immune responses (4). RELM-α was originally identified in inflammatory zones in an experimental allergic airway disease model and was therefore also termed found in inflammatory zone 1 (FIZZ1) (5,6). Moreover, related studies found that RELM-α is a hallmark signature gene of activated macrophages. RELM-α expression is tightly regulated by IL-13, IL-4 and signal transducer and activator of transcription protein signaling pathway (7). RELM-α also has a key functions in fibrosis in the setting of experimental asthma (8). Notably, RELM-α was identified in the gastrointestinal tract and is strongly linked with the induction of Th2 immune responses and mucosal immunity, involving inflammatory bowel disease (9). Accumulating the evidence also indicates that RELM-α is involved in the angiogenesis of endothelial cells and induces vascular remodeling (10). Yet, RELM-α expression in gastric cancer and its correlation with gastric cancer clinicopathological characteristics remain unclear.

In the present study, we first examined RELM-α expression in 92 paired cases of gastric cancer and adjacent non-cancerous...
mucosa tissues and in SGC7901 and MKN45 gastric cancer cell lines to investigate the relevance of RELM-α expression in gastric cancer and its functional mechanism. In addition, an in vitro study was performed to observe the silencing effect of RELM-α on gastric cancer cells, to investigate its effective mechanism in order to determine its use as a potential therapeutic target.

Materials and methods

Patients and specimens. Ninety-two cases of gastric cancer and adjacent non-cancerous tissues were collected at Ruijin Hospital and Ruijin Hospital North, Shanghai Jiaotong University School of Medicine from April 2007 to February 2013. Tissue samples for diagnostic purposes were obtained with the consent of each patient. All tumor specimens and corresponding adjacent non-cancerous tissues were fixed in 10% buffered formalin, embedded in paraffin and then made into continuous 4-µm tissue sections for examination. The study group consisted of 52 males and 40 females, aged 18-92 years, with an average age of 61±14 years. Each specimen was analyzed by routine pathological analysis and was classified according to the pathological criteria published by the World Health Organization (4th edition) and the tumor-node-metastasis (TNM) staging system of the American Joint Committee on Cancer Staging Manual (7th edition) and the Japanese Gastric Cancer Association Guidelines (3rd edition). None of the gastric cancer patients had synchronous cancers or previous gastrointestinal diseases, nor had undergone abdominal surgery, chemotherapy or radiotherapy prior to specimen collection. The present study was performed with pre-approval from the ethics committees of the participating hospitals.

Immunohistochemistry. Gastric cancer tissue paraffin sections were placed in citrate buffer (pH 6.0) for antigen retrieval. The negative control antibody was replaced by phosphate-buffered saline (PBS). The procedure was in accordance with the SP detection instructions (Maixin Co., Fujian, China). Paraffin sections (4-µm) were used for histological staining. The diluted density of rabbit anti-human RELM-α, vascular endothelial growth factor (VEGF), CD34 antibody (Santa Cruz Biotechnology, Santa Cruz, CA, USA) and adjacent non-cancerous tissues were fixed with the horseradish peroxidase (HRP)-labeled anti-rabbit IgG antibody (Maixin Co.). The immunostained specimens were observed first under low-power magnification (x40), and then the most dense area of microvessel sections was selected under high-power magnification (x400; the surface area of every vision field being 0.785 mm²). The number of microvessels in three vision fields was counted according to the number of single endothelial cells or endothelial cell clusters showing brownish yellow granules in the cytoplasm. The sections were observed first under low-power magnification (x40), and then the most dense area of microvessel sections was selected under high-power magnification (x400; the surface area of every vision field being 0.785 mm²). The number of microvessels was counted according to the number of single endothelial cells or endothelial cell clusters showing brownish yellow granules in the cytoplasm. The sections were observed first under low-power magnification (x40), and then the most dense area of microvessel sections was selected under high-power magnification (x400; the surface area of every vision field being 0.785 mm²). The number of microvessels in three vision fields was counted and averaged as MVD of the given specimen.

In vitro

Cell culture. Two gastric cancer cell lines (MKN45 and SGC7901) and the 293 cell line were obtained from Ruijin Hospital, Shanghai Jiaotong University School of Medicine. Cells were cultured in RPMI-1640 medium supplemented with 10% fetal bovine serum (FBS) (Gibco-BRL, Gaithersburg, MD, USA) and incubated in 5% CO₂ at 37°C in 95% humidity.

Construction of RELM-α-siRNA. The specific silencing of the human RELM-α gene expression was achieved by the siRNA technique.

The study used replication defective adenovirus serotype 5/F35 (Ad5/F35) as the vector. Ad5/F35-RELM-α-siRNA was constructed by Hongming Bio. (Shanghai, China) using a previously described method (12). RELM-α-siRNA was chemically synthesized, and subcloned into the PDC316-MCMV-EGFP transfer plasmid (Mierobix Biosystems Co., Mississauga, ON, Canada). This plasmid was cotransfected into 293 cells, along with a fragment of the plasmid containing the Ad5/F35 adenoviral vector (Bengyuanzhengang Bio., Beijing, China). Additionally, an Ad5/F35 containing an empty expression cassette was constructed for use as a control (Ad5/F35-vector). All of the viral constructs were similar with the exception of the trans-gene, and the production and purification procedures were identical. The SGC7901 and MKN45 cells at 50-60% confluency in a total volume of 500 ml/well growth medium, were randomly allocated into 3 groups: cells treated with PBS served as control cells; cells treated with Ad5/F35-RELM-α-siRNA at a multiplicity of infection (MOI) of 10; and cells treated with the Ad5/F35-vector (MOI of 5) for 24 h for further examination.

RELM-α expression in cells. Total RNA was isolated from the cells using TRIzol reagent kits (Gibco-BRL, Rockville, MD, USA). The cDNA obtained from this reaction was mixed with PCR buffer, MgCl₂, dNTPs, Taq DNA polymerase and human RELM-α gene-specific primers [the primer sequences of RELM-α: forward primer, 5’-GGC TGG ATG ACT CCT ACT GG-3’ and reverse primer, 5’-TGT GTT GGA GCT GAT-3’ (synthesis by Sangon Biotech Co., Shanghai, China)] and amplified in an automated thermal cycler (Bio-Rad MJ Mini; Bio-Rad Laboratories, Inc., Hercules, CA, USA). The conditions of RT-PCR were as follows: 1 cycle for 5 min at 95°C, 35 cycles for 45 sec at 94°C, for 45 sec at 55°C, for 1 min at 72°C, and 1 cycle for 10 min at 72°C. The PCR products were separated by electrophoresis on 1.2% agarose gels and stained with ethidium bromide. The densities of the cDNA bands were analyzed by scanning densitometry using GelDoc 2000 software (Bio-Rad Laboratories, Inc.). The band densities were normalized to GAPDH (the primer sequence...
at a density of 1x10^5 cells were treated with or without Ad5/F35-RELM-α was replaced with serum-free RPMI-1640 for 12 h, and the RPMI-1640 supplemented with 10% FBS. Then, the medium to remove any floating cells and cultured in 5% CO_2 for 200-µl sterile pipette tip. The media were carefully changed wound was created by scraping the cell monolayer with a 20 µl MTT (5 mg/ml) was added to each well. Four hours later, 100 µl of dimethyl sulfoxide was added to each well after the medium was removed. Finally, the absorbance (A) was detected with an enzyme calibrator at 570 nm. The cell viability = (A of study group/A of control group) x 100%.

Scratch wound-healing assay. To measure cell motility, 4x10^4 cells were seeded into 6-well plates. A central linear wound was created by scraping the cell monolayer with a 200-µl sterile pipette tip. The media were carefully changed to remove any floating cells and cultured in 5% CO_2 at 37°C. The migration of cells into the denuded areas in the scraped region was calculated at 48 h, respectively. The wound at 0 h was considered 100% of the average gap.

Cell invasion assays. Invasion assays were performed using Transwell chambers (Corning Inc., Corning, NY, USA). Briefly, 2x10^4 cells/dish were seeded in a 10-cm dish overnight in RPMI-1640 supplemented with 10% FBS. Then, the medium was replaced with serum-free RPMI-1640 for 12 h, and the cells were treated with or without Ad5/F35-RELM-α-siRNA (MOI of 10) or transfected with the Ad5/F35 vector (MOI of 5). After 24 h, 20 µl MTT (5 mg/ml) was added to each well. Four hours later, 100 µl of dimethyl sulfoxide was added to each well after the medium was removed. Finally, the absorbance (A) was detected with an enzyme calibrator at 570 nm. The cell viability = (A of study group/A of control group) x 100%.

Cell viability assay. The effect of RELM-α silencing on gastric cell viability was monitored using the 3-(4,5-dimethylthiazol-2-yl)-2,5-diphenyltetrazolium bromide (MTT) (Sigma, St. Louis, MO, USA) colorimetric assay. In brief, a total of 2x10^4 cells were seeded in 96-well plates. After 24 h, the cells were treated with Ad5/F35-RELM-α-siRNA (MOI of 10) or transfected with the Ad5/F35 vector (MOI of 5). After 24 h, 20 µl MTT (5 mg/ml) was added to each well. Four hours later, 100 µl of dimethyl sulfoxide was added to each well after the medium was removed. Finally, the absorbance (A) was detected with an enzyme calibrator at 570 nm. The cell viability = (A of study group/A of control group) x 100%.

Western blot analysis. The levels of nuclear factor (NF)-κB p65, vascular endothelial growth factor (VEGF) and matrix metalloproteinase (MMP)-9 proteins were investigated in each group using western blotting. The cells were washed twice with PBS and then homogenized in RIPA buffer (Biyuntian Co., Shanghai, China). Following centrifugation at 12,000 x g at 4°C for 10 min, the supernatant was collected and stored at 80°C. Protein concentration of each sample was determined by the BCA protein assay (Biyuntian Co.). Each sample was adjusted to a desired protein content of 40 µg, then denatured in loading buffer and separated by electrophoresis on 9% SDS polyacrylamide gel at 100 V for 120 min. The separated proteins were transferred to polyvinylidene difluoride membranes using transfer buffer at 200 mA for 90 min. The membranes were blocked with 5% non-fat dry milk in Tris-buffered saline (TBS)-0.1% Tween for 1 h at room temperature, washed three times for 10 min each in TBS-0.1% Tween, and incubated with a primary antibody including NF-κB p65, VEGF and MMP-9 (Santa Cruz Biotechnology) at a 1:1,000 dilution in TBS-0.1% Tween overnight at 4°C, respectively. After three 10-min washings in TBS-0.1% Tween, the membranes were incubated with a secondary antibody, HRP-conjugated rat anti-rabbit immunoglobulin G (Kangcheng Inc., Shanghai, China) for 1 h at room temperature. After washing, the membranes were detected using enhanced chemiluminescence methods (Amersham Biosciences, Piscataway, NJ, USA), and then were scanned for densitometry using Bio-Image Analysis System (Bio-Rad Laboratories, Inc.). For quantification, GAPDH was determined in a similar manner with the anti-GAPDH antibody (diluted to 1:1,000; Santa Cruz Biotechnology) as an endogenous control for other proteins.

Electrophoretic and mobility shift assay (EMSA). The activity of NF-κB of cells was examined by EMSA reagent kits (Pierce Chemical Co., Rockford, IL, USA). Nuclear extracts of cells were prepared from gastric cancer cells at 24 h after stimulation. The biotinylated double-stranded DNA probe sequence of NF-κB was: sense, 5’-AGT TGA GGG GAC TTT CCC GTC TGT C-3’ and reverse primer, 5’-CAGCCT TCT CCA TGG TGG TGA AGA-3’; synthesis by Sangon Biotech Co.) GCT TGT C-3’. The binding of NF-κB p65, VEGF and MMP-9 proteins were investigated in each group. The nuclear extracts of gastric cancer cells were obtained by cell lysis and nuclear extraction. Briefly, the cells were harvested and lysed in 1 ml of cold RIPA buffer (Biyuntian Co., Rockford, IL, USA) containing 1% Nonidet P-40 and 50 µg/ml poly(dI:dC) (Biyuntian Co.). After lysis, nuclear extracts were collected and washed two times with PBS. Then, the nuclear extracts were precleared by incubation with 5 µl of goat anti-rabbit IgG (Sigma) for 1 h at 4°C. The biotinylated double-stranded DNA oligonucleotide containing NF-κB sites was added to the nuclear extract at a final concentration of 50 µg/ml and incubated at 4°C for 20 min. The DNA-protein complexes were captured with 5 µl of streptavidin-conjugated magnetic beads, washed three times with PBS, and then washed once with 2X sample buffer. The complexes were resolved by 12% SDS-PAGE and transferred to polyvinylidene difluoride membranes using transfer buffer at 200 mA for 90 min. The membranes were blocked with 5% non-fat dry milk in Tris-buffered saline (TBS)-0.1% Tween for 1 h at room temperature, washed three times for 10 min each in TBS-0.1% Tween, and incubated with a primary antibody including NF-κB p65, VEGF and MMP-9 (Santa Cruz Biotechnology) at a 1:1,000 dilution in TBS-0.1% Tween overnight at 4°C, respectively. After three 10-min washings in TBS-0.1% Tween, the membranes were incubated with a secondary antibody, HRP-conjugated rat anti-rabbit immunoglobulin G (Kangcheng Inc., Shanghai, China) for 1 h at room temperature. After washing, the membranes were detected using enhanced chemiluminescence methods (Amersham Biosciences, Piscataway, NJ, USA), and then were scanned for densitometry using Bio-Image Analysis System (Bio-Rad Laboratories, Inc.). For quantification, GAPDH was determined in a similar manner with the anti-GAPDH antibody (diluted to 1:1,000; Santa Cruz Biotechnology) as an endogenous control for other proteins.

Statistical analysis. All statistical analyses were carried out using the SPSS software statistical package (version 13.0; SPSS, Inc., Chicago, IL, USA). The relationships between the differential expression of RELM-α and clinicopathological characteristics were evaluated by the χ^2 test. The one-way analysis of variance (ANOVA) with Dunnett’s multiple comparison tests was used for comparisons. A P-value <0.05 was considered to indicate a statistically significant result.

Results

RELM-α expression in the gastric cancer cases. Expression of RELM-α and VEGF showed a predominant localization to the cytoplasm or on the cell membrane in the tissue specimens. Specimens with positive expression are presented in Fig. 1. The results showed that positive expression of RELM-α was found in 64.1% (59/92) of the gastric cancer tissues compared with 16.3% (15/92) of the adjacent normal tissues.

Among the 92 cases of gastric cancer, 59 (64.1%) cases had positive expression and 33 (35.8%) cases had negative expression of RELM-α; which showed a statistically significant
difference (P<0.05). Moreover, among the gastric cancer cases, 77 (83.6%) cases had positive expression and 15 (16.4%) cases had negative expression of VEGF; which achieved a statistically significant difference (P<0.05).

Furthermore, the clinical relevance was confirmed by the observation that RELM-α expression was correlated with the prognosis in gastric cancer (Table I). Tumor stage and size were significantly associated with high expression of RELM-α protein (P<0.05). No correlation was observed between RELM-α protein expression and age, gender, degree of differentiation, and gross classification of tumors (P>0.05). In addition, the gastric cancer cases with positive expression of RELM-α and VEGF (48/92, 52.1%) were compared with those having negative expression of RELM-α and VEGF (4/92, 4.3%), which showed a difference and thus may be correlated with each other (Table II).

As shown in Fig. 2, the MVD of tumors was determined by CD34 staining. The MVD value of the 92 gastric cancer specimens was 17.23±8.94, while the MVD value in the 92 adjacent normal tissues was 6.58±2.32, showing a statistically
significant difference between the gastric cancer and adjacent normal tissues (P<0.05).

In the 59 gastric cancer cases with positive RELM-α expression and the 33 cases with negative of RELM-α expression, the MVD was 22.23±6.79 and 8.30±3.93, respectively, which showed a statistically significant difference (P<0.05). Meanwhile, in the 77 gastric cancer cases with positive VEGF expression and the 15 cases with negative VEGF expression, the MVD was 19.12±8.49 and 7.53±2.74, respectively, which showed a statistically significant difference (P<0.05).

The tumor size, tumor stage and MVD value in the RELM-α-positive/VEGF-positive gastric cancer patients were found to be higher when compared with these parameters in the RELM-α-negative/VEGF-negative gastric cancer patients (P<0.01) (Table II).

In vitro Effect of the silencing of RELM-α expression on gastric cancer cells. The levels of RELM-α expression in the SGC7901 and MKN45 cells were assessed by western blotting and RT-PCR assays methods (Fig. 3). The data showed that at 24 h following Ad5/F35-RELM-α-siRNA treatment, RELM-α protein levels were decreased in the SGC7901 and MKN45 cells, yet not in the cells treated with the Ad5/F35-vector and the control cells (P<0.01) (Fig. 3A). Similar to the western blotting data, the SGC7901 and MKN45 cells with Ad5/F35-RELM-α-

* vs. RELM-α (+)/VEGF (+) patients, P<0.01. RELM-α, resistin-like molecule-α; VEGF, vascular endothelial growth factor; MVD, microvessel density.
Effects of RELM-α silencing on cell proliferation. We aimed to assess whether RELM-α silencing suppressed the growth of gastric cancer cells (Fig. 4). The results showed that the percentage of viable cells following Ad5/F35-RELM-α-siRNA treatment for 24 h was reduced in the two gastric cancer cell lines when compared with the control and Ad5/F35 vector-treated cells as determined by MTT assay (P<0.01).

Furthermore, to examine the effect of RELM-α silencing on cell motility, an in vitro scratch wound-healing assay was performed. The results indicated that the Ad5/F35-RELM-α-siRNA-treated cells significantly (P<0.01) exhibited slower repair of the scratched wound when compared with the control and the RELM-α vector-treated cells (Fig. 5). This result suggests that the silencing of RELM-α expression inhibited cell migration.

To further investigate the effect of RELM-α silencing on cell invasion, the invasive ability of the cells was examined using a Transwell chamber assay (Fig. 6). After incubation for 24 h, the number of control and Ad5/F35 vector-treated cells which had invaded the polycarbonate membrane of the Matrigel chamber was ~2-fold higher than that of the Ad5/F35-RELM-α-siRNA-treated group, respectively, which showed a statistically significant difference (P<0.01). These results provide evidences that RELM-α plays a role in enhancing the metastasis of gastric cancer cells.

The mechanism involved in RELM-α silencing in gastric cancer cells. To determine the effect of RELM-α on NF-κB activation, NF-κB-DNA binding activity was determined in the different treated and control gastric cancer cells by EMSA. In Fig. 7, after treatment with Ad5/F35-RELM-α-siRNA for
Figure 5. The migration of SGC7901 and MKN45 cells was investigated by scratch wound healing assay in each group. *P<0.01 vs. the Ad5/F35-RELM-α-siRNA-treated group. RELM-α, resistin-like molecule-α.

Figure 6. The invasiveness of SGC7901 and MKN45 cells was determined using a Matrigel-coating chamber in each group. *P<0.01 vs. the Ad5/F35-RELM-α-siRNA-treated group. RELM-α, resistin-like molecule-α.
24 h, the NF-κB-DNA binding activity was decreased when compared with the Ad5/F35 vector-treated and control cells.

The expression level of p65, as the active subunit of NF-κB, was significantly decreased in the Ad5/F35-RELM-α-siRNA-treated cells, compared with the level in the Ad5/F35-vector and control cells (P<0.01). Additionally, the downstream proteins regulated by NF-κB, MMP-9 and VEGF, were also suppressed in the Ad5/F35-RELM-α-siRNA-treated cells when compared with the Ad5/F35 vector-treated and the control cells, respectively (P<0.01) (Fig. 8).

**Discussion**

RELM-α belongs to the RELM family of cysteine-rich secretory proteins that share homology with resistin. To date, four members of this family have been identified: RELM-α,
RELM-β, FIZZ-3 and RELM-γ (13). Some studies in animals suggest that the members of the RELM family have important pro-inflammatory and remodeling roles. For example, RELM-α was first discovered in the ‘inflammatory zone’ of mice with allergic pulmonary inflammation and has also been described as a hypoxia-inducible mitogenic factor implicated in hypoxia-associated vascular remodeling. RELM-α was found to be upregulated in several infectious and inflammatory settings, including infection, allergic airway inflammation and colitis (14,15). Related research demonstrated that RELM-α promotes intestinal APC activation, Th17 cell responses and intestinal inflammation (16). A previous study demonstrated that RELM-α was consistently detectable in the serum, and the expression levels in colonic inflammation (17). In addition, substantial evidence exists that RELM-α regulates pro-inflammatory cytokines (IL-6 and TNF-α) and activates intracellular pro-inflammatory NF-κB signaling pathway (18,19).

Angiogenesis is a process of neovascular formation from pre-existing blood vessels, which consists of sequential steps for vascular destabilization, lumen formation and vascular stabilization. Furthermore, angiogenesis is a critical process in the invasion, growth and metastasis of most solid tumors, and induction of angiogenesis represents one of the major hallmarks of cancer (20). Angiogenesis is complex and involves a large number of molecules including VEGF and MMP-9 (21). VEGF is a key mediator in the angiogenesis of cancers through signaling pathways including phosphoinositide 3 kinase (PI3K)/Akt and NF-κB, which stimulate endothelial cells of microvessels to proliferate, migrate and alter their pattern of gene expression (22). The high levels of VEGF in tumors are predictive of high metastatic risk and poor prognosis (23). In the present study, VEGF expression was highly correlated with angiogenesis, malignancy and metastasis of gastric cancer. MVD has been used to evaluate the angiogenic activity of tumors (24). In the present study, the MVD value was significantly increased in the gastric cancer tissues when compared with that in the adjacent normal tissues. This finding suggests that angiogenesis plays an important role in the development of gastric cancer. Furthermore, upregulation of RELM-α was observed in the gastric cancer but not in the normal gastric tissues. In addition, expression of RELM-α was correlation with the expression of VEGF and the MVD in the tissues. In conclusion, our results suggest that RELM-α is a novel independent prognostic marker with functional relevance in gastric cancer, yet its related mechanisms remain unclear.

In the present study, the results demonstrated for the first time that RELM-α was silenced in gastric cancer cell lines by siRNA treatment. We then explored the molecular mechanisms of RELM-α, to identify key regulators of the RELM-α mediated effect on gastric cancer.

The activation of NF-κB and its signaling pathways are central coordinators of innate and adaptive immune responses. More recently, it has become clear that NF-κB also has a critical role in cancer development and progression. Inactivation of NF-κB decreases tumor multiplicity or size in cancer by downregulating anti-apoptotic gene expression and dampened production of growth-stimulating cytokines (25). Moreover, NF-κB also regulates tumor angiogenesis and invasiveness (26). NF-κB p65 is sequestered in the cytoplasm by its inhibitor proteins in cells, and in response to a variety of stimuli, its inhibitor proteins can be phosphorylated resulting in the translocation of cytoplasmic NF-κB p65 into the nucleus, thereby activating the transcription of NF-κB target genes (27).

In keeping with this, in the present study, the activation of NF-κB was increased in gastric cancer, yet RELM-α silencing decreased its activation. Furthermore, the expression of NF-κB p65 was decreased in gastric cancer cells by Ad5/F35-RELM-α-siRNA treatment. Previous studies have described RELM-α expression in vascular smooth muscle and endothelial cells of the remodeling vasculature in animals (28). The present study also demonstrated that RELM-α expression was positively correlated with angiogenesis of gastric cancers. Based on this result, the study further explored the relationship between RELM-α and VEGF expression.

A recent study suggested that RELM-α upregulated VEGF expression in mouse epithelial cells via an NF-κB-dependent pathway (29) which is in accordance with our present study that found that the VEGF production in cells was significantly attenuated by NF-κB signaling pathway inhibitor that was involved in RELM-α silencing in gastric cancer. On the other hand, MMP-9 is a downstream target gene of NF-κB, and has also been found to be upregulated in gastric cancer cells. Furthermore, it has been reported that the expression of MMP-9 is closely correlates with tumor angiogenesis (30). MMP-9 has also been shown to trigger an angiogenic switch during tumor progression by releasing VEGF (31). We found that cells with silenced expression of RELM-α exhibited decreased expression of MMP-9 and VEGF protein when compared to the control cells. Thus, RELM-α is involved in the development of gastric cancer by the NF-κB-MMP-9/VEGF pathway.

In summary, the positive expression of RELM-α in the gastric cancer tissues was related to tumor size, clinical stage and promoted the progression of gastric cancer by angiogenesis. The anti-angiogenesis following RELM-α silencing may be involved in the regulation of the production of angiogenesis factor VEGF and NF-κB signaling pathway activation. Inhibition of RELM-α expression was associated with the inhibition of tumor progression and invasiveness in gastric cancer. Finally, RELM-α targeted gene and protein therapy can be used as an effective molecular targeted therapy for gastric cancer.
